Abstract

In order to address the multi-directional nature of constraint logic programs, recent optimizing compilers generate several versions of a procedure and optimize them independently. Reordering, i.e., moving constraints towards the end of a clause, plays a fundamental role in this optimization: it may lead to significant improvements in performance by bypassing the constraint solver entirely. This paper focuses on CLP over linear real constraints, and studies two abstract domains, i.e., `LSign` and `LInt`, which can be used to decide at compile time when constraints can be safely reordered. The domain `LSign` was originally proposed by Marriott and Stuckey. Its fundamental ideas consist of abstracting coefficients by signs and of keeping multiplicity information on constraints. `LInt` is a new, and infinite, domain which is similar in nature to `LSign`, except that signs are replaced by intervals of rational numbers. A comprehensive description of the two domains is given, together with some very preliminary evidence showing that the domains are precise enough to perform the intended optimizations on small programs.

Keywords: Static analysis; Abstract domains; Optimizations; Constraints

1. Introduction

Constraint logic programming (CLP) [19] is a generalization of logic programming, where constraint solving over a suitable domain replaces unification as the basic operation of the language. Many CLP languages have been defined in the last decade on computation domains such as linear real constraints (e.g., Refs. [20,38,4] integers (e.g., Ref. [37]), Booleans (e.g., Refs. [3,4]), and nonlinear real constraints (e.g., Ref. [30]).

CLP languages offer many challenges for optimizing compilers since constraint solving, its basic operation, may be quite expensive in general. It is thus natural to try to specialize it whenever appropriate. The optimization problem is also exacerbated by the fact that CLP programs can be multi-directional (i.e., they may be used with different combinations of input/output parameters). Hence, a given program may be appropriate for some uses, while being "sub-optimal" for some others.

This paper focuses on CLP($\Re_{Lin}$) programs [20,39,35], i.e. on constraint logic programs over linear real constraints, and the approach to CLP optimization proposed in Ref. [27]. This methodology consists of refining constraints into tests and assignments, of removing redundant constraints (i.e., constraints which are implied by the constraint store), and of reordering constraints to maximize refinements and removals, while preserving the same search space. The optimizations are specific to the domain $\Re$ of real constraints but similar optimizations can be applied to other domains as well. These optimizations are global in nature, and require information about the macro properties of the program in order to be automated successfully.

Among these various optimizations, reordering is probably the most fundamental. The need for reordering comes from the multi-directional nature of CLP programs. A traditional technique to address this issue in recent optimizing compilers (e.g., Refs. [31,23,24,32]) consists of generating one version of each procedure for each use and of specializing each version independently. Reordering is fundamental in this optimization: it consists of moving constraints toward the end of the clause so that they can be turned into tests or assignments. Of course, reordering should only be applied when postponing the constraints does not change the search space explored by the program (and thus does not change the termination behaviour of the program). In other words, reordering makes it possible to bypass the constraint solver while preserving the same search space, thus improving the performance of the program in many cases.

This paper studies two abstract domains, `LSign` and `LInt`, which can be used to decide when to reorder CLP programs. `LSign` is an abstract domain originally proposed in Ref. [28] and further studied in Ref. [33]. Its fundamental ideas consist of abstracting coefficients by signs and of keeping multiplicity information on constraints. `LInt` is a new, and infinite, domain which is similar in nature to `LSign`, except that signs are replaced by intervals of rational numbers. Note that other domains have been proposed for the analysis of CLP($\Re_{Lin}$) programs (e.g., Refs. [10,11,14,15]) and these domains are potentially useful for reordering as well. However, as acknowledged in Ref. [15], they are less precise than `LSign` and, as shown later in this paper, applying `LSign` itself is not easy in practice. Hence, the study of `LSign` and `LInt` gives another entry point on the analysis of CLP($\Re_{Lin}$) programs.

The focus of the paper is to give a comprehensive presentation of these domains together with their correctness proofs and their application to reordering. As shown in Ref. [33], `LSign` raises some interesting issues and obtaining correct abstract operations is non trivial. In addition, as shown later on in this paper, applying `LSign` in a naive way in an optimizing compiler is unsatisfactory: "obvious" optimizations cannot be performed automatically if no special care is taken. The paper illustrates these problems, proposes solutions, and provides some preliminary empirical evi-

dence that the resulting algorithms are precise enough to optimize small programs. This paper does not discuss the reordering algorithm and its correctness proof: they are discussed in Ref. [36] and deserve an independent treatment.

As far as LSign is concerned, the paper redefines the domain of [28] to fix some loose ends and to simplify the correctness proofs. It proposes a new ordering capturing the intended meaning of [28] and shows that two LSign descriptions can be ordered in polynomial time. It also proposes a more precise algorithm for projection. Finally, the paper discusses how LSign can be used to detect the conditional satisfiability of constraint stores, an operation which is fundamental to reorder CLP($\Re_{Lin}$) programs. This operation, which was never discussed previously, raises some subtle practical issues which are studied at length.

As far as LInt is concerned, the paper contains the first presentation of the domain, and proposes a practical and precise widening operator. The operator has the original property of using LSign to guide the widening process. The paper also contains some preliminary empirical evidence of the overhead of LInt over LSign.

The rest of this paper is organized as follows. Section 2 explains why reordering is so fundamental in CLP($\Re_{Lin}$) optimizations. Section 3 describes the concrete objects and operations. Section 4 and Section 5 give a detailed presentation of the abstract domains LSign and LInt, respectively. Section 6 presents the preliminaries experimental results. Section 7 concludes the paper. The proofs of the results can be found in the technical report version of this paper [34]. Only sketches of these proofs are given here for space reasons.

2. Why reordering is important?

To motivate the paper, it is interesting to study an example of optimization in some detail. Consider the following CLP($\Re_{Lin}$) program [20] which relates various parameters in a mortgage computation. This program will be used as running example in the paper.

Example 2.1.

```
mg(P,T,R,B) :- T = 0, B = P.
mg(P,T,R,B) :- T > 0, P >= 0, P1 = P * 1.01 - R, T1 = T - 1,
               mg(P1,T1,R,B).
```

The predicate mg relates the principal (P), number of monthly installments (T), monthly repayment (R) and final balance (B) of a mortgage that has a fixed monthly interest rate of 1%. The most interesting feature of this program is its multi-directionality. For example, the query

```
:- mg(P,4,200,0)
```

computes the principal of a mortgage having four installments of 200 units each, with a final balance of 0. The answer is P = 780.39. The program can also be used to compute the monthly repayment given the principal. For example, the query

```
:- mg(800,4,R,0)
```

gives the answer R = 205.02. An even more interesting query is to find out the repayments such that each repayment is less than 200 units and there are at most six installments. This is given by

$$:\text{-}\ \mathtt{R} < 200, \mathtt{T} \leqslant 6, \mathtt{mg}(800, \mathtt{T}, \mathtt{R}, 0)$$

and gives the answers T = 5, R = 164.83 and T = 6, R = 138.04.

In general, the predicate mg above can be used to compute the (complicated) relations between any of the parameters in the mortgage computation because of the general constraint solver embedded in the language. For some of the above uses, however, this generality is not needed and it is possible to generate a completely deterministic program which does not even resort to constraint solving. In the rest of this section, we present how this is achieved by the first pass of the optimizing compiler [36]. The first pass of the compiler may be viewed as a source to source transformation, transforming the source program into another (richer) source program which may contain, not only constraints, but also assignments and tests as basic operations. The source to source transformation is organized in three main phases: reordering, removal, and refinement.

Consider the case where mg is used with P and R fixed (i.e., they are constrained to take a value) and T and B are unconstrained. The first step of the compiler tries to move constraints to a place in the clause where, roughly speaking, they can be specialized into tests or into assignments. More precisely, an inequality is moved to a place where all its variables are fixed at runtime, while an equation is moved to a place where all its variables or all its variables but one are fixed at runtime. In reordering goals in a clause, the compiler should make sure that the search space explored by the program is preserved in order to guarantee termination and to avoid significant slowdowns. On our running example, the compiler postpones $\mathtt{T} > 0$ in the second clause until after the recursive call. Informally speaking, this is possible due to the fact that $\mathtt{T} > 0$ is always consistent with the constraint stores occurring in the recursive call to mg and, consequently, $\mathtt{T} > 0$ does not prune the search space. This information can be formally derived through an LSign or LInt analysis. Note also that, when postponed until after the recursive call, $\mathtt{T} > 0$ may be specialized into a test, since T is fixed. Similarly, T1 = T - 1 can be moved until after the recursive call, since T is now unconstrained before the recursive call and hence it cannot prune the search space. The resulting program becomes:

$$\begin{aligned}
&\mathtt{mg}(\mathtt{P}, \mathtt{T}, \mathtt{R}, \mathtt{B}) :\text{-}\ \mathtt{T} = 0,\ \ \mathtt{B} = \mathtt{P},\\
&\mathtt{mg}(\mathtt{P}, \mathtt{T}, \mathtt{R}, \mathtt{B}) :\text{-}\ \mathtt{P} \geqslant 0,\ \ \mathtt{P1} = \mathtt{P} \ * \ 1.01 - \mathtt{R},\ \ \mathtt{mg}(\mathtt{P1}, \mathtt{T1}, \mathtt{R}, \mathtt{B}),\\
&\qquad\qquad\qquad \mathtt{T} = \mathtt{T1} + 1,\ \ \mathtt{T} > 0.
\end{aligned}$$

Once the program is reordered, other optimizations can take place. A second step consists of detecting redundant constraints (i.e., constraints implied by the constraint store each time they are selected). These constraints can be removed, since they do not add information to the constraint store. In our running example, this is the case of $\mathtt{T} > 0$ after reordering, since informally speaking, the second argument is assigned to zero in the first clause and incremented by one in the recursive clause.[1] Once again, this fact can be proven formally through abstract interpretation using the do-

[1] Note that this constraint is useful for other uses of the program.

main LSign or LInt or other domains such as the convex hull domain of [8]. The resulting program is as follows:

$$\texttt{mg(P,T,R,B)} :\texttt{-}\ \texttt{T} = 0,\ \ \texttt{B} = \texttt{P},$$
$$\texttt{mg(P,T,R,B)} :\texttt{-}\ \texttt{P} \geqslant 0,\ \ \texttt{P1} = \texttt{P}\ \ * \ 1.01 - \texttt{R},\ \ \texttt{mg(P1,T1,R,B)},\ \ \texttt{T} = \texttt{T1} + 1.$$

Finally, the last step of the source to source transformation specializes constraints into tests and assignments whenever possible. A constraint can be specialized into a test if the compiler shows that, at runtime, all its variables are fixed. An equation Var = Exp can be transformed into an assignment if the compiler shows that, at runtime, Var is unconstrained and Exp is a fixed expression. In our running example, it can be shown that, after reordering and removal, T and B are unconstrained in all calls to mg. Once again, this information can be deduced from domains such as LSign and LInt. Also P and R are constrained to take a value in all calls to mg. As a consequence, the constraints in the first clause becomes assignments, while the second clause has two assignments and a test.

$$\texttt{mg(P,T,R,B)} :\texttt{-}\ \texttt{T} := 0,\ \ \texttt{B} := \texttt{P},$$
$$\texttt{mg(P,T,R,B)} :\texttt{-}\ \texttt{P?} \geqslant 0,\ \ \texttt{P1} := \texttt{P}\ \ * \ 1.01 - \texttt{R},\ \ \texttt{mg(P1,T1,R,B)},\ \ \texttt{T} := \texttt{T1} + 1.$$

It is interesting to observe that the resulting program does not invoke the constraint solver. It is essentially a Prolog program enhanced with a rational arithmetic component. As a consequence, traditional Prolog transformations and optimizations can now be applied. For instance, the techniques of [9] can be used to transform our final program into a tail-recursive program. Similarly, efficient instructions can be generated for the tests and assignments [21].

3. The concrete domain

Abstract interpretation [6] is a general methodology to design static analyses of programs. The basic intuition is to infer some properties of a program, not by executing it on its traditional computation domain, but rather on an abstract domain. The abstract domain should of course be designed to approximate the properties of interest with reasonable precision and with reasonable computer resources. Traditionally, an abstract interpretation is constructed in four steps: a semantics of the language is defined, called the standard semantics; the standard semantics is transformed into a collecting (concrete) semantics; [2] the collecting semantics is abstracted into an abstract semantics; the abstract semantics (or a subset of it) is computed.

This paper follows this methodology for the analysis of CLP programs. The paper does not describe each of these steps in detail, since the focus here is on the abstract domains. It suffices to say that the concrete semantics for CLP is a natural extension to CLP of the logic programming semantics presented in many papers. It captures the top-down execution of CLP programs using a left-to-right computation rule, and ignores the clause selection rule. The concrete semantics is defined for

[2] This second step is needed in general because the analysis aims at giving some information about the results of a computation for a set of input values, not a single input value.

normalized CLP programs and it manipulates sets of constraint stores (multisets of linear constraints). The rest of this section formally defines the concrete concepts necessary for this paper. Readers interested in a comprehensive presentation of the various steps should refer to [36]. See also Refs. [11,14,15,24,23] for applications of static analysis to CLP.

Programs. A CLP($\Re_{Lin}$) program is a (possibly empty) sequence of clauses in which each clause has a head and a body. A head is an atom, i.e. an expression of the form p(t_1,...,t_n) where t_1,...,t_n are terms. A term is a variable (e.g. X) or a rational number. A body is either true (the empty body), a goal (procedure call), a constraint (constraint solving) or a sequence of these. In the following, variables are denoted by uppercase letters, constraints by the letter c, possibly subscripted or superscripted. The constraints of CLP($\Re_{Lin}$) can be specified as follows:

Definition 3.1. Let t_1 and t_2 be two linear expressions constructed with variables, rational numbers, and the operations $+, *, -$ and $/$. A constraint is a relation $t_1\ \delta\ t_2$ with $\delta \in \{>, \geqslant, =, \neq, \leqslant, <\}$.

It is convenient to normalize CLP($\Re_{Lin}$) programs in order to simplify the analysis. Normalized programs are defined in terms of sets P_i ($i \geqslant 0$) representing the set of predicate symbols of arity i and of an infinite sequence of variables $x_1, x_2, \ldots$ A *normalized program* is a (possibly empty) sequence of clauses, in which each clause has a head and a body. The head of a clause has the form $p(x_1, \ldots, x_n)$, where $p \in P_n$. The body of a clause is a (possibly empty) sequence of literals where each literal is either a predicate call or a linear constraint. A predicate call has the form $p(x_{i_1}, \ldots, x_{i_m})$, where $p \in P_m$ and the variables $x_{i_1}, \ldots, x_{i_m}$ are all distinct. Linear constraints are defined below. Any given CLP($\Re_{Lin}$) program may be transformed into an equivalent normalized program by simple rewriting rules [2].

Concrete objects. The concrete objects manipulated by our concrete semantics are *linear constraints and multisets of linear constraints*. Given a set of variables $D = \{x_1, \ldots, x_n\}$, a linear constraint over D is an expression of the form $c_0\ \delta\ \sum_{i=1}^{n} c_i x_i$, where c_i are rational numbers and $\delta \in \{=, <, \leqslant, >, \geqslant, \neq\}$. The set of linear constraints over D is denoted by C_D. A constraint store over D is simply a multiset of linear constraints over D. The set of constraint stores over D is denoted by CS_D and is ordered by standard multiset inclusion.[3] In the following, we denote multiset union by $\cup$, linear constraints by the letter λ, constraint stores by the letter θ and sets of constraint stores by the letter Θ, all possibly subscripted. If λ is a linear constraint $c_0\ \delta\ \sum_{i=1}^{n} c_i x_i$, $\lambda[i]$ denotes the coefficient c_i, and $op(\lambda)$ denotes the operator δ. We denote the set of variables $\{x_1, \ldots, x_n\}$ by D_n for any n. If θ is a constraint store over the set of variables D, $\mathrm{dom}(\theta) = D$. The projection of a constraint store θ on the set of variables D is denoted $\theta_{/D}$. If θ is a constraint store over $D = \{x_1, \ldots, x_n\}$ and $x \in D$, θ_x^+, θ_x^- and θ_x^0 represent all constraints λ in θ whose coefficient for variable x is respectively strictly positive, strictly negative, and zero. We

[3] Observe that this is a partial order, and that constraint stores, not comparable by the order relation, can be equivalent. This is harmless, as the analysis is always conservative, but it may introduce some redundancies.

use $\mathtt{Var}(\theta)$ to denote the set of variables with non-zero coefficients in θ. We also denote by $\mathscr{I}$ the set $\{i \mid x_i \in D\}$.

Concrete operations. The concrete semantics of CLP programs requires three main concrete operations: addition of a constraint to a constraint store, projection of a constraint store on some variables, and union of constraint stores. We now define these concrete operations in more detail.

Upper bound. Let $\Theta_1, \ldots, \Theta_m$ be sets of constraint stores on D_n. $\mathtt{UNION}(\Theta_1, \ldots, \Theta_m)$ returns a set of constraint stores that represents all the constraint stores in Θ_i $(1 \leqslant i \leqslant m)$. Operation UNION is used to compute the result of a predicate given the results of its individual clauses. It is specified as follows.

Specification 1. Let $\Theta_1, \ldots, \Theta_m$ be sets of constraint stores on D_n. Then

$$\mathtt{UNION}(\Theta_1, \ldots, \Theta_m) = \Theta_1 \cup \cdots \cup \Theta_m.$$

Addition of a constraint. Let Θ be a set of constraint stores on D_n and λ be a constraint on D_n. $\mathtt{AI\_ADD}(\lambda, \Theta)$ returns a set of constraint stores that represents the result of adding the constraint λ to each of the constraint stores in Θ. Operation AI_ADD is used when a constraint is encountered in the program.

Specification 2. Let Θ be a set of constraint stores on D_n and λ be a constraint on D_n.

$$\mathtt{AI\_ADD}(\lambda, \Theta) = \{\theta \cup \{\lambda\} \mid \theta \in \Theta\}.$$

Projection of a constraint store. Let Θ be a set of constraint stores on variables D, and let V be a subset of these variables. $\mathtt{PROJECT\_SET}(\Theta, V)$ returns the set of constraint stores obtained by projecting Θ on $R = D \setminus V$. It is specified as follows.

Specification 3. Let Θ be a set of constraint stores on D, $V \subseteq D$, and $R = D \setminus V$. Then

$$\mathtt{PROJECT\_SET}(\Theta, V) = \{\theta_{/R} \mid \theta \in \Theta\}.$$

This operation is used in many phases in the concrete semantics, e.g. just before a procedure call to project the constraint stores on the call variables, or at the exit of a clause to project the constraint stores on the head variables.

4. The abstract domain LSign

In this section, we present the abstract domain LSign. First, Section 4.1 presents the abstract domain used to approximate linear constraints and multisets of linear constraints. Sections 4.2 and 4.3 contain the operations and applications of the domain. This is followed by a brief presentation of the power domain in Section 4.4.

4.1. The domain

As mentioned in the introduction, the domain was first introduced in Ref. [28] and then revisited in Ref. [33]. The presentation here is based on [33] which clearly

separates multiplicity information from the abstract constraints.[4] The presentation is motivated by the fact that it makes it easy to define the concretization function compositionally by identifying the semantic objects clearly. In contrast, [28] uses an approach based on an abstraction function and approximation relations.

The first key idea is the notion of an abstract constraint which abstracts a concrete constraint by replacing each coefficient by its sign.

Our definitions assume $D = \{x_1, \ldots, x_n\}$. An *operator* is an element of $\mathtt{Op} = \{<, \leqslant, =\}$. Operators are denoted by the letter δ.

Definition 4.1 (*Signs*). A *sign* is an element of $\mathtt{Sign} = \{0, \oplus, \ominus, \top\}$. $\mathtt{Sign}$ is ordered by $s_1 \sqsubseteq s_2 \Longleftrightarrow (s_1 = s_2) \vee (s_2 = \top)$. The (monotone) concretization function $Cc : \mathtt{Sign} \to 2^{\mathfrak{R}}$ is defined as

$$Cc(0) = \{0\};\ Cc(\oplus) = \{c \mid c \in \mathfrak{R} \wedge c > 0\};$$
$$Cc(\ominus) = \{c \mid c \in \mathfrak{R} \wedge c < 0\};\ Cc(\top) = \mathfrak{R}.$$

Definition 4.2 (*Abstract constraints*). An *abstract constraint* over D is an expression of the form $s_0 \delta \sum_{i=1}^{n} s_i x_i$, where s_i is a sign and δ is an operator. The set of abstract constraints over D is denoted by A_D and is partially ordered by

$$s_0 \delta \sum_{i=1}^{n} s_i x_i \sqsubseteq s'_0 \delta \sum_{i=1}^{n} s'_i x'_i \Longleftrightarrow \bigwedge_{i=0}^{n} (s_i \sqsubseteq s'_i).$$

The (monotone) concretization function $Cc : A_D \to C_D$ is defined as:

$$Cc\left(s_0 \delta \sum_{i=1}^{n} s_i x_i\right) = \left\{ c_0 \delta \sum_{i=1}^{n} c_i x_i \mid c_i \in Cc(s_i)\ (1 \leqslant i \leqslant n) \right\}.$$

Abstract constraints are denoted by the letter σ, possibly subscripted.

Example 4.1. The abstract constraint $\top = \oplus\mathtt{P} + \oplus\mathtt{R}$ represents both the constraint $3 = \mathtt{P} + \mathtt{R}$ and $-3 = 2\mathtt{P} + 5\mathtt{R}$ but not the constraint $3 = -\mathtt{P} + \mathtt{R}$.

The second key concept is the notion of an abstract constraint with multiplicity which represents a multiset of constraints. The multiplicity information specifies the size of the multiset. We consider three multiplicities, `One`, `ZeroOrOne`, and `Any`, which are used respectively to represent a multiset of size 1, a multiset of size 0 or 1, or a multiset of arbitrary size.

Definition 4.3 (*Multiplicities*). A *multiplicity* is an element of $\mathtt{Mult} = \{\mathtt{One}, \mathtt{ZeroOrOne}, \mathtt{Any}\}$. $\mathtt{Mult}$ is ordered by $\mathtt{One} \sqsubseteq \mathtt{ZeroOrOne} \sqsubseteq \mathtt{Any}$. Multiplicities are denoted by the letter μ, possibly subscripted.

We now turn to abstract constraints with multiplicities. Recall that elements of CS_D are multisets of linear constraints.

[4] This was motivated by previous work on sequences [1] which separates properties of the elements of the sequences from properties of the sequence.

Definition 4.4 (*Abstract constraints with multiplicity*). An *abstract constraint with multiplicity* over D is an expression of the form $\langle \sigma, \mu \rangle$, where σ is an abstract constraint over D and μ is a multiplicity. The set of abstract constraints with multiplicity over D is denoted by AM_D and is ordered by

$$\langle \sigma_1, \mu_1 \rangle \sqsubseteq \langle \sigma_2, \mu_2 \rangle \Longleftrightarrow \sigma_1 \sqsubseteq \sigma_2 \wedge \mu_1 \sqsubseteq \mu_2.$$

The (monotone) concretization function $Cc : AM_D \to CS_D$ is defined as:

$$Cc(\langle \sigma, One \rangle) = \{\{\lambda\} \mid \lambda \in Cc(\sigma)\},$$
$$Cc(\langle \sigma, \texttt{ZeroOrOne} \rangle) = \{\emptyset\} \cup \{\{\lambda\} \mid \lambda \in Cc(\sigma)\},$$
$$Cc(\langle \sigma, \texttt{Any} \rangle) = \{\emptyset\} \cup \{\{\lambda_1, \ldots, \lambda_m\} \mid m \geqslant 1 \wedge \lambda_i \in Cc(\sigma)\ (1 \leqslant i \leqslant m)\}.$$

Abstract constraints with multiplicities[5] are denoted by the letter γ, possibly subscripted. Moreover, if γ is $\langle \sigma, \mu \rangle$, $cons(\gamma)$ denotes σ and $mult(\gamma)$ denotes μ.

Example 4.2. The abstract constraint with multiplicity $\langle \top = \oplus \mathtt{P} + \oplus \mathtt{R}, \mathtt{One} \rangle$ represents only multisets of size 1, e.g., $\{3 = \mathtt{P} + \mathtt{R}\}$. $\langle 0 \leqslant \oplus \mathtt{P} + \ominus \mathtt{R}, \mathtt{Any} \rangle$ represents multisets of any size, e.g., $\emptyset$, $\{0 \leqslant 3\mathtt{P} - \mathtt{R}\}$ and $\{0 \leqslant 3\mathtt{P} - \mathtt{R}, 0 \leqslant 2\mathtt{P} - 3\mathtt{R}\}$.

We are now in position to define the abstract stores of the domain, which abstract the constraint stores in the concrete domain.

Definition 4.5 (*Abstract stores*). An *abstract store* over D is a set β of abstract constraints with multiplicities. The set of abstract stores is denoted by AS_D. The concretization function $Cc : AS_D \to CS_D$ is defined in two stages. The first captures the syntactic form of the abstract store.

$$Cc_i(\emptyset) = \{\emptyset\},$$
$$Cc_i(\{\gamma\} \cup \beta) = \{\theta_1 \underline{\cup} \theta_2 \mid \theta_1 \in Cc(\gamma) \wedge \theta_2 \in Cc_i(\beta)\} \quad \gamma \notin \beta.$$

The second captures the extension to equivalence classes in the concrete domain.

$$Cc(\beta) = \{\theta \mid \theta \leftrightarrow \theta_i \wedge \theta_i \in Cc_i(\beta)\}.$$

Abstract stores are denoted by the letter β, possibly subscripted.

Example 4.3. The abstract store $\beta = \{\langle \top = \oplus \mathtt{P} + \oplus \mathtt{R}, \mathtt{One} \rangle,\ \langle 0 \leqslant \oplus \mathtt{P} + \ominus \mathtt{R}, \mathtt{Any} \rangle\}$ represents constraint stores with at least one constraint, and their equivalence classes. For example $\{3 = \mathtt{P} + \mathtt{R}\} \in Cc_i(\beta)$ and $\{3 = \mathtt{P} + \mathtt{R},\ 0 \leqslant 2\mathtt{P} - 3\mathtt{R}\} \in Cc_i(\beta)$. Further, $\{3 = \mathtt{P} + \mathtt{R},\ 9 \leqslant 5\mathtt{P}\} \in Cc(\beta)$ because $\{3 = \mathtt{P} + \mathtt{R},\ 9 \leqslant 5\mathtt{P}\} \leftrightarrow \{3 = \mathtt{P} + \mathtt{R},\ 0 \leqslant 2\mathtt{P} - 3\mathtt{R}\}$.

It remains to define the ordering on abstract stores. Our goal is to make sure that $\beta_1 \sqsubseteq \beta_2$ implies that $Cc(\beta_1) \subseteq Cc(\beta_2)$ to obtain a monotone concretization function. The ordering relation is non-trivial and requires the following concepts.

[5] Ref. [28] contains one additional multiplicity *OneOrMore* which is obtained easily in our domain by including one constraint with multiplicity `One` and one constraint with multiplicity `Any`. Note also that all inequalities are defined with a multiplicity `Any` in Ref. [28].

Definition 4.6 (*Definite, possible and indefinite constrains*). Let γ be an abstract constraint with multiplicity. γ is a *definite* abstract constraint iff $mult(\gamma) = \texttt{One}$. γ is a *possible* abstract constraint iff $mult(\gamma) = \texttt{ZeroOrOne}$. It is an *indefinite* abstract constraint otherwise. The *definite portion* of β, denoted by $\texttt{Def}(\beta)$, is the set of definite constraints of β. The *possible portion* of β, denoted by $\texttt{Pos}(\beta)$, is the set of possible constraints of β. The *indefinite portion* of β, denoted by $\texttt{Indef}(\beta)$, is the set of indefinite constraints of β.

Definition 4.7 (*Ordering function*). Let β_1 and β_2 be two abstract stores. An *ordering function* of β_1 to β_2 is a function $f : \beta_1 \to \beta_2$ satisfying
1. $\forall \gamma \in \beta_1 : \gamma \sqsubseteq f(\gamma)$,
2. $\forall \gamma_1, \gamma_2 \in \beta_1 : \gamma_1 \neq \gamma_2 \Rightarrow f(\gamma_1) \neq f(\gamma_2) \vee f(\gamma_1) \in \texttt{Indef}(\beta_2)$,
3. $\texttt{Def}(\beta_2) \subseteq range(f)$.

Definition 4.8 (*Ordering on abstract stores*). Let β_1 and β_2 be two abstract stores. $\beta_1 \sqsubseteq \beta_2$ if there exists an ordering function f of β_1 to β_2.

This definition of ordering indicates that we reason only on the syntactic form of the abstract stores. The first condition states that, for each abstract constraint with multiplicity in β_1, say γ, there exists an abstract constraint with multiplicity in β_2, say $f(\gamma)$, that approximates it. The next two conditions concern the number of constraints. The second condition requires that each definite constraint and each possible constraint in β_2 be used at most once. The third condition requires that each definite constraint in β_2 be used at least once.[6]

Example 4.4. Consider the following abstract constraints with multiplicity.

$$\gamma_1 = \langle \oplus = \oplus\texttt{P} + \oplus\texttt{R}, \texttt{One}\rangle, \quad \gamma_4 = \langle \oplus = \oplus\texttt{P} + \oplus\texttt{R}, \texttt{One}\rangle,$$
$$\gamma_2 = \langle \oplus = \ominus\texttt{P} + \oplus\texttt{R}, \texttt{One}\rangle, \quad \gamma_5 = \langle \oplus = \ominus\texttt{P} + \top\texttt{R}, \texttt{Any}\rangle,$$
$$\gamma_3 = \langle \oplus = \ominus\texttt{P} + \oplus\texttt{R}, \texttt{Any}\rangle, \quad \gamma_6 = \langle \oplus = \oplus\texttt{P} + \top\texttt{R}, \texttt{One}\rangle\rangle.$$

$\{\gamma_1, \gamma_2\} \sqsubseteq \{\gamma_4, \gamma_5\}$ and the ordering function is defined by $f(\gamma_1) = \gamma_4$ and $f(\gamma_2) = \gamma_5$. Moreover, $\{\gamma_1, \gamma_2, \gamma_3\} \sqsubseteq \{\gamma_4, \gamma_5\}$ and the function is defined by $f(\gamma_1) = \gamma_4$, $f(\gamma_2) = \gamma_5$, and $f(\gamma_3) = \gamma_5$. Finally, $\{\gamma_3, \gamma_4\} \not\sqsubseteq \{\gamma_1, \gamma_5, \gamma_6\}$, since there is no function that can cover both γ_1 and γ_6 with only $\{\gamma_3, \gamma_4\}$.

It can be proved that the ordering on abstract stores is transitive and reflexive, leading to the following theorem.

Theorem 4.1 (The ordering relation). $\sqsubseteq$: *$AS_D \times AS_D$ is a pre-order.*

We now turn to the first main result of this section: the monotonicity of the concretization function for abstract stores. The proof uses several lemmas, one of them

[6] Notice that $\{\langle \oplus = \oplus x_1 + \oplus x_2, \texttt{One}\rangle\}$ is smaller than $\{\langle \oplus = \oplus x_1 + \top x_2, \texttt{One}\rangle\}$, and $\{\langle \oplus = \oplus x_1 + \ominus x_2, \texttt{One}\rangle\}$ is smaller than $\{\langle \oplus = \oplus x_1 + \top x_2, \texttt{One}\rangle\}$, but it is not true that $\{\langle \oplus = \oplus x_1 + \oplus x_2, \texttt{One}\rangle, \langle \oplus = \oplus x_1 + \ominus x_2, \texttt{One}\rangle\}$ is smaller than $\{\langle \oplus = \oplus x_1 + \top x_2, \texttt{One}\rangle\}$. The latter holds in Ref. [28], but apparently it is not what was intended. This problem showed up when trying to prove the correctness of the abstract operations of `LSign` using the ordering defined in Ref. [28], and made it impossible, obviously.

(i.e., the lifting function lemma) being fundamental in all consistency proofs. Note that we sometimes abuse notation by writing expressions like $\lambda_1 \neq \lambda_2$ to mean that λ_1 and λ_2 are two different constraints or two different occurrences of the same constraint in a multiset. These abuses should be clear from the context. We also write $|S|$ to denote the cardinality of a set or of a multiset. We define the notion of lifting function which is the counterpart of the ordering function for a pair (concrete store, abstract store).

Definition 4.9 (*Lifting function*). Let β be an abstract store and θ a concrete constraint store. A *lifting function* of θ to β is a function $f : \theta \to \beta$ satisfying:
1. $\forall \lambda \in \theta$: $\lambda \in Cc(cons(f(\lambda)))$,
2. $\forall \lambda_1, \lambda_2 \in \theta$: $\lambda_1 \neq \lambda_2 \Rightarrow (f(\lambda_1) \neq f(\lambda_2) \vee f(\lambda_1) \in \mathtt{Indef}(\beta))$,
3. $\mathtt{Def}(\beta) \subseteq range(f)$.

As mentioned, the following lemma is the cornerstone of most proofs in this section.

Lemma 4.1 (Lifting function lemma). *Let β be an abstract store and θ a concrete constraint store. $\theta \in Cc_i(\beta)$ if and only if there exists a lifting function f of θ to β.*

Proof (*sketch*). The proof proceeds by induction on $|\beta|$. The basic case is obvious. For the induction step, assume that the hypothesis holds for all abstract stores whose cardinality is not greater than n. We show that it holds for abstract stores of cardinality $n+1$. Consider an abstract store β satisfying $|\beta| = n+1$ and let β be $\{\gamma\} \cup \beta'$, where $\gamma \notin \beta'$ and $|\beta'| = n$. By Definition 4.5,

$$Cc_i(\beta) = Cc_i(\{\gamma\} \cup \beta') = \{\theta_1 \underline{\cup} \theta' \mid \theta_1 \in Cc(\gamma) \wedge \theta' \in Cc_i(\beta')\}.$$

($\Rightarrow$) Let $\theta \in Cc_i(\beta)$. Hence $\theta = \theta_1 \underline{\cup} \theta'$, where $\theta_1 \in Cc(\gamma) \wedge \theta' \in Cc_i(\beta')$. By hypothesis, there exists a lifting function f' of θ' to β'. Define a function $f : \theta \to \beta$ as

$$f(\lambda) = \begin{cases} f'(\lambda) & \text{if } \lambda \in \theta', \\ \gamma & \text{if } \lambda \in \theta_1. \end{cases}$$

The proof consists of showing that f is a lifting function of θ to β.

($\Leftarrow$) Let f be a lifting function of θ to $\beta = \{\gamma\} \cup \beta'$. Let $\theta_1 = \{\lambda \mid \lambda \in \theta \wedge f(\lambda) = \gamma\}$. Then $\forall \lambda \in \theta_1 : \lambda \in Cc(cons(\gamma))$ by Definition 4.9 and $\theta_1 \in Cc(\gamma)$ by Definition 4.1. Let $\theta = \theta_1 \underline{\cup} \theta'$ and consider the function $f' : \theta' \to \beta'$ defined by $f'(\lambda) = f(\lambda)$ for all $\lambda \in \theta'$. The proof consists of showing that f' is a lifting function of θ' to β'. Then, by hypothesis, $\theta' \in Cc_i(\beta')$ and, by Definition 4.5, $\theta_1 \underline{\cup} \theta' \in Cc_i(\{\gamma\} \cup \beta')$. □

Example 4.5. Consider the following abstract constraints with multiplicity

$$\gamma_1 = \langle \oplus = \oplus \mathtt{P} + \oplus \mathtt{R}, \mathtt{One} \rangle, \quad \gamma_2 = \langle \oplus = \oplus \mathtt{P} + \oplus \mathtt{R}, \mathtt{One} \rangle,$$
$$\gamma_3 = \langle \oplus = \ominus \mathtt{P} + \top \mathtt{R}, \mathtt{Any} \rangle, \quad \gamma_4 = \langle \oplus = \oplus \mathtt{P} + \top \mathtt{R}, \mathtt{One} \rangle,$$

and concrete constraints

$$\lambda_1 = 2 = 2\mathtt{P} + 3\mathtt{R}, \qquad \lambda_2 = 3 = -2\mathtt{P} + 2\mathtt{R},$$
$$\lambda_3 = 1 = -3\mathtt{P} + 2\mathtt{R}, \quad \lambda_4 = 4 = 4\mathtt{P} + 3\mathtt{R}.$$

$\{\lambda_1, \lambda_2\} \in Cc_i(\{\gamma_2, \gamma_3\})$ and the lifting function is defined by $f(\lambda_1) = \gamma_2$ and $f(\lambda_2) = \gamma_3$. Moreover, $\{\lambda_1, \lambda_2, \lambda_3\} \in Cc_i(\{\gamma_2, \gamma_3\})$ and the function is defined by $f(\lambda_1) = \gamma_2, f(\lambda_2) = \gamma_3$, and $f(\lambda_3) = \gamma_3$. Finally, $\{\lambda_3, \lambda_4\} \notin Cc_i(\{\gamma_1, \gamma_2, \gamma_4\})$, since there is no function that can cover all three of γ_1, γ_2 and γ_4 with only λ_3 and λ_4.

We are now in position to state the first main result of this section.

Theorem 4.2 (Monotonicity of concretization function w.r.t. ordering relation). *If β_1 and β_2 are two abstract stores then*
(i) $\beta_1 \sqsubseteq \beta_2 \Rightarrow Cc_i(\beta_1) \subseteq Cc_i(\beta_2)$.
(ii) $\beta_1 \sqsubseteq \beta_2 \Rightarrow Cc(\beta_1) \subseteq Cc(\beta_2)$.

Proof (*sketch*). (i) Let $\beta_1 \sqsubseteq \beta_2$ and $\theta \in Cc_i(\beta_1)$. We need to show that $\theta \in Cc_i(\beta_2)$. By Lemma 4.1, there exists a lifting function f of θ to β_1. By Definition 4.8, there exists an ordering function g of β_1 to β_2. Consider the function $g \circ f$. The proof just shows that $g \circ f$ is a lifting function of θ to β_2. (ii) Let $\beta_1 \sqsubseteq \beta_2$ and $\theta \in Cc(\beta_1)$. By definition of Cc, there exists $\theta_i \in Cc_i(\beta_1)$ s.t. $\theta \leftrightarrow \theta_i$. By part (i), $\theta_i \in Cc_i(\beta_2)$. Hence, by definition of Cc, $\theta \in Cc(\beta_2)$. □

For subsequent sketches of proof where the result is stated in two parts, the first part relating to Cc_i and the second part relating to Cc, we only give the sketch of proof for the first part. The extension for Cc follows the outline of the proof above.

4.2. Abstract operations

We now study the implementation of the abstract operations of `LSign`. We start by the implementation of the ordering relation, continue with the addition of a constraint and the upper bound operation, and conclude with projection.

The problem of *ordering abstract stores*, i.e. of deciding whether $\beta_1 \sqsubseteq \beta_2$, could be solved simply by enumerating all functions from β_1 to β_2 to determine whether one of them is an ordering function. However, this would lead to an exponential algorithm in the size of the stores. In this section, we show that we can do much better by reducing the ordering problem to a maximum weighted bipartite graph matching problem.

Definition 4.10 (*Bipartite graph*). A graph $G = (V, E)$ is bipartite if V can be partitioned into two sets V_1, V_2 such that $(u, v) \in E$ implies either $u \in V_1 \wedge v \in V_2$ or $u \in V_2 \wedge v \in V_1$.

Definition 4.11 (*Maximum weighted bipartite graph matching problem*). Let $G = (V, E)$ be a weighted bipartite graph. A matching M on G is a set of edges no two of which have a common vertex. The weight of M is the sum of its edge weights. The *maximum weighted bipartite graph matching problem* is that of finding a matching of maximum weight.

The key ideas behind the reduction are as follows. The first set of vertices corresponds to the constraints of β_1. The second set of vertices contains a vertex for each constraint in $\texttt{Def}(\beta_2)$, a vertex for each constraint in $\texttt{Pos}(\beta_2)$, and $|\beta_1|$ vertices for

each constraint in $\texttt{Indef}(\beta_2)$, since these constraints can be used several times and the matching problem requires that each vertex appears at most once in a solution. The edges connect vertices from the first set to vertices of the second set only if the constraint in the first set is smaller or equal to the constraint in the second set. This requirement makes sure that the first property of ordering is guaranteed. To ensure the third property, we specify the weights in a special way to encourage the covering of the definite constraints in β_2. The second property will follow from the definition of a matching.

Definition 4.12. Let β_1 and β_2 be two abstract stores. The *matching graph* of β_1 to β_2 is a (weighted bipartite) graph $G = (V, E)$ such that

$$
\begin{aligned}
V &= V_1 \cup V_2 \cup V_3 \cup V_4,\\
V_1 &= \{\gamma_1 \mid \gamma_1 \in \beta_1\},\\
V_2 &= \{\gamma_2 \mid \gamma_2 \in \texttt{Def}(\beta_2)\},\\
V_3 &= \{\gamma_2 \mid \gamma_2 \in \texttt{Pos}(\beta_2)\},\\
V_4 &= \{\gamma_2^{\gamma_1} \mid \gamma_2 \in \texttt{Indef}(\beta_2) \wedge \gamma_1 \in \beta_1\},
\end{aligned}
$$

$$
\begin{aligned}
E &= E_2 \cup E_3 \cup E_4,\\
E_2 &= \{(\gamma_1, \gamma_2) \mid \gamma_1 \in V_1 \wedge \gamma_2 \in V_2 \wedge \gamma_1 \sqsubseteq \gamma_2\},\\
E_3 &= \{(\gamma_1, \gamma_2) \mid \gamma_1 \in V_1 \wedge \gamma_2 \in V_3 \wedge \gamma_1 \sqsubseteq \gamma_2\},\\
E_4 &= \{(\gamma_1, \gamma_2^{\gamma_1}) \mid \gamma_1 \in V_1 \wedge \gamma_2^{\gamma_1} \in V_4 \wedge \gamma_1 \sqsubseteq \gamma_2\},
\end{aligned}
$$

$$
\mathit{weight}(e) = \begin{cases} 2 & \text{if } e \in E_2,\\ 1 & \text{if } e \in E_3 \cup E_4. \end{cases} \quad \forall e \in E,
$$

Implementation 1 (*Ordering*). Let β_1 and β_2 be two abstract stores. Let G be the matching graph β_1 to β_2. $\beta_1 \sqsubseteq \beta_2$ returns *true* iff the maximum matching of G has weight $|\beta_1| + |\texttt{Def}(\beta_2)|$.

We now prove the correctness of the implementation.

Lemma 4.2. *Let β_1 and β_2 be two abstract stores and G be a matching graph of β_1 to β_2. $\beta_1 \sqsubseteq \beta_2$ if and only if G has a matching of weight $|\beta_1| + |\texttt{Def}(\beta_2)|$.*

Proof (*sketch*). ($\Rightarrow$) Let $\beta_1 \sqsubseteq \beta_2$. By Definition 4.8, there exists an ordering function f of β_1 to β_2. Consider the set given by $M = M_2 \cup M_3 \cup M_4$ where,

$$
\begin{aligned}
M_2 &= \{(\gamma_1, \gamma_2) \mid \gamma_1 \in V_1 \wedge \gamma_2 \in V_2 \wedge \gamma_2 = f(\gamma_1)\},\\
M_3 &= \{(\gamma_1, \gamma_2) \mid \gamma_1 \in V_1 \wedge \gamma_2 \in V_3 \wedge \gamma_2 = f(\gamma_1)\},\\
M_4 &= \{(\gamma_1, \gamma_2^{\gamma_1}) \mid \gamma_1 \in V_1 \wedge \gamma_2^{\gamma_1} \in V_4 \wedge \gamma_2 = f(\gamma_1)\}.
\end{aligned}
$$

The proof consists of showing that M is a matching of the appropriate weight.

($\Leftarrow$) Let G have a matching M of weight $|\beta_1| + |\mathtt{Def}(\beta_2)|$. Then $M = M_2 \cup M_3 \cup M_4$, where

$$M_2 = \{(\gamma_1, \gamma_2) | \gamma_1 \in V_1 \wedge \gamma_2 \in V_2\},$$

$$M_3 = \{(\gamma_1, \gamma_2) | \gamma_1 \in V_1 \wedge \gamma_2 \in V_3\},$$

$$M_4 = \{(\gamma_1, \gamma_2^{\gamma_1}) | \gamma_1 \in V_1 \wedge \gamma_2^{\gamma_1} \in V_4\}.$$

We define f by $f(\gamma_1) = \gamma_2$ if $(\gamma_1, \gamma_2) \in M_2$, or $(\gamma_1, \gamma_2) \in M_3$, or $(\gamma_1, \gamma_2^{\gamma_1}) \in M_4$ and $f(\gamma_1) = \textit{undefined}$ otherwise. The proof consists of showing that f is a total function from β_1 to β_2, and that f is an ordering function of β_1 to β_2. □

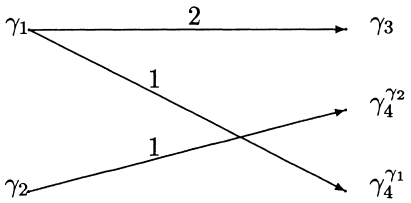
Theorem 4.3. *The implementation of ordering satisfies its definition.*

Proof. This follows from Lemma 4.2 and the fact that there cannot exist a matching of cost greater than $|\beta_1| + |\mathtt{Def}(\beta_2)|$ when testing $\beta_1 \sqsubseteq \beta_2$. □

Example 4.6. Consider the abstract stores $\beta_1 = \{\gamma_1, \gamma_2\}$ and $\beta_2 = \{\gamma_3, \gamma_4\}$, where

$$\gamma_1 = \langle \oplus = \oplus\mathtt{P} + \top\mathtt{R}, \mathtt{One}\rangle, \quad \gamma_2 = \langle \oplus = \oplus\mathtt{P} + \ominus\mathtt{R}, \mathtt{Any}\rangle,$$
$$\gamma_3 = \langle \oplus = \top\mathtt{P} + \top\mathtt{R}, \mathtt{One}\rangle, \quad \gamma_4 = \langle \oplus = \oplus\mathtt{P} + \top\mathtt{R}, \mathtt{Any}\rangle.$$

The matching graph G of β_1 to β_2 is given below:



We have that $\beta_1 \sqsubseteq \beta_2$ because the maximum matching of G has weight 3.

The following result gives the complexity of the ordering implementation.

Theorem 4.4. *Let β_1 and β_2 be two abstract stores. The complexity of checking if $\beta_1 \sqsubseteq \beta_2$ is not more than* $O(|\beta_1|^2 |\beta_2|^2 \log |\beta_1||\beta_2|)$.

Proof. This follows from Ref. [13] which proved that the weighted bipartite matching problem can be solved in time $O(|V|^2 \log |V| + |V||E|)$ i.e. $O(|\beta_1|^2 |\beta_2|^2 \log |\beta_1||\beta_2|)$ and the definition of the matching graph. □

We now turn to the basic operation of CLP languages: *adding a constraint to a constraint store.* We make the operation slightly more general than needed to simplify the rest of the section.

Specification 4 (*Adding an abstract constraint with multiplicity*). Operation $\uplus : AS_D \times AM_D \to AS_D$ should satisfy the following consistency condition. $\forall \theta_1, \theta_2 \in CS_D, \forall \beta \in AS_D, \forall \gamma \in AM_D$:

$$\theta_1 \in Cc(\beta) \ \wedge \ \theta_2 \in Cc(\gamma) \Rightarrow \theta_1 \underline{\cup} \theta_2 \ \in \ Cc(\beta \uplus \gamma).$$

Definition 4.13. Let β be an abstract store and γ be an abstract constraint with multiplicity. The operation to add an abstract constraint to an abstract store is defined by

$$\beta \uplus \gamma = \begin{cases} \beta \cup \{\gamma\} & \text{if } \gamma \notin \beta, \\ \beta \cup \{\langle \sigma, \mathtt{Any} \rangle\} & \text{if } \gamma = \langle \sigma, \mu \rangle \in \beta. \end{cases}$$

Informally speaking, the operation adds γ to β if γ is not in β. Otherwise, the multiplicity needs to be adjusted to take into account the new constraint. This is done by setting the multiplicity to Any. Although the operation is very simple, the proof of its consistency is non-trivial and indicates why it is convenient to consider multisets (and not sets) of constraints in the concrete semantics.

Example 4.7. Let $\beta = \{\langle \oplus = \oplus \mathtt{T}, \mathtt{One} \rangle, \langle 0 \leqslant \oplus \mathtt{P}, \mathtt{One} \rangle\}$. Adding the abstraction of $0 \leqslant 2\mathtt{R} + 3\mathtt{B}$, i.e. $\langle 0 \leqslant \oplus \mathtt{R} + \oplus \mathtt{B}, \mathtt{One} \rangle$, to β leads to

$$\beta' = \{\langle \oplus = \oplus \mathtt{T}, \mathtt{One} \rangle,\ \langle 0 \leqslant \oplus \mathtt{P}, \mathtt{One} \rangle,\ \langle 0 \leqslant \oplus \mathtt{R} + \oplus \mathtt{B}, \mathtt{One} \rangle\}.$$

Adding the abstraction of $0 \leqslant 3\mathtt{R} + 4\mathtt{B}$, i.e. $\langle 0 \leqslant \oplus \mathtt{R} + \oplus \mathtt{B}, \mathtt{One} \rangle$, to β' gives the store $\{\langle \oplus = \oplus \mathtt{T}, \mathtt{One} \rangle,\ \langle 0 \leqslant \oplus \mathtt{P}, \mathtt{One} \rangle,\ \langle 0 \leqslant \oplus \mathtt{R} + \oplus \mathtt{B}, \mathtt{One} \rangle,\ \langle 0 \leqslant \oplus \mathtt{R} + \oplus \mathtt{B}, \mathtt{Any} \rangle\}$.

Theorem 4.5. *Let β be an abstract store and γ be an abstract constraint with multiplicity.*

(i) *If $\theta_1 \in Cc_i(\beta)$ and $\theta_2 \in Cc(\gamma)$, then $\theta_1 \underline{\cup} \theta_2 \in Cc_i(\beta \uplus \gamma)$.*

(ii) *If $\theta_1 \in Cc(\beta)$ and $\theta_2 \in Cc(\gamma)$, then $\theta_1 \underline{\cup} \theta_2 \in Cc(\beta \uplus \gamma)$.*

Proof (*sketch*). Let $\gamma = \langle \sigma, \mu \rangle$. If $\theta_1 \in Cc_i(\beta)$, then there exists a lifting function f of θ_1 to β by Lemma 4.1. Consider the function $f' : \theta_1 \underline{\cup} \theta_2 \to \beta \uplus \gamma$ given by

$$f'(\lambda) = f(\lambda) \qquad \text{for all } \lambda \in \theta_1,$$

$$f'(\lambda) = \begin{cases} \gamma & \text{if } \gamma \notin \beta, \\ \langle \sigma, \mathtt{Any} \rangle & \text{if } \gamma = \langle \sigma, \mu \rangle \in \beta. \end{cases} \quad \text{for all } \lambda \in \theta_2.$$

The proof consists of showing that f' is a lifting function of $\theta_1 \underline{\cup} \theta_2$ to $\beta \uplus \gamma$. Operation $\uplus$ is useful for the implementation of other operations. In fact, it is convenient to generalize it further. □

Definition 4.14. Let β and β' be abstract stores.

$$\beta \biguplus \beta' = \begin{cases} \beta & \text{if } \beta' = \emptyset, \\ (\beta \uplus \gamma) \biguplus \beta'' & \text{if } \beta' = \{\gamma\} \cup \beta'',\ \gamma \notin \beta''. \end{cases}$$

Lemma 4.3. *Let β and β' be abstract stores.*

(i) *If $\theta \in Cc_i(\beta)$ and $\theta' \in Cc_i(\beta')$, then $\theta \underline{\cup} \theta' \in Cc_i(\beta \biguplus \beta')$.*

(ii) *If $\theta \in Cc(\beta)$ and $\theta' \in Cc(\beta')$, then $\theta \underline{\cup} \theta' \in Cc(\beta \biguplus \beta')$.*

Example 4.8. The following example is based on the mortgage program mg/4 of Example 2.1. We have that $\theta \in Cc_i(\beta)$, where $\theta = \{0 < \mathtt{T},\ 0 \leqslant \mathtt{P},\ 0 = \mathtt{P} * 1.01 - \mathtt{R} - \mathtt{P1},\ 1 = \mathtt{T} - \mathtt{T1}\}$ and $\beta = \{\langle 0 < \oplus \mathtt{T}, \mathtt{One} \rangle,\ \langle 0 \leqslant \oplus \mathtt{P},\ \mathtt{One} \rangle,\ \langle 0 = \oplus \mathtt{P} + \ominus \mathtt{R} + \ominus \mathtt{P1}, \mathtt{One} \rangle,\ \langle \oplus = \oplus \mathtt{T} + \ominus \mathtt{T1}, \mathtt{One} \rangle\}$. Also $\theta' \in Cc_i(\beta')$, where $\theta' = \{0 = \mathtt{T1},\ 0 = \mathtt{B} - \mathtt{P1}\}$ and $\beta' = \{\langle 0 = \oplus \mathtt{T1}, \mathtt{One} \rangle, \langle 0 = \oplus \mathtt{B} + \ominus \mathtt{P1}, \mathtt{One} \rangle\}$. This gives by Lemma 4.3 that $\theta \underline{\cup} \theta' \in Cc(\beta \biguplus \beta')$.

We now turn to the *upper bound of constraint stores.* The operation UNION: $AS_D \times AS_D \to AS_D$ is specified as follows.

Specification 5. UNION: $AS_D \times AS_D \to AS_D$ should satisfy the following consistency condition. $\forall\theta \in CS_D, \forall\beta_1 \in AS_D, \forall\beta_2 \in AS_D$:

$$\theta \in Cc(\beta_1) \vee \theta \in Cc(\beta_2) \Rightarrow \theta \in Cc(\texttt{UNION}(\beta_1, \beta_2)).$$

We first define the upper bound of signs and multiplicities.

Definition 4.15 (*Upper bound on signs*). The upper bound operation on signs $\sqcup$:Sign $\times$ Sign $\to$ Sign is defined as $s_1 \sqcup s_2 = s_1$ if $s_1 = s_2$, $\top$ otherwise

Definition 4.16 (*Upper bound on multiplicities*). The upper bound operation on multiplicities $\sqcup$:Mult $\times$ Mult $\to$ Mult is defined as $\mu_1 \sqcup \mu_2 = max(\mu_1, \mu_2)$.

We now turn to the upper bound operation on abstract stores. Note first that LSign has no least upper bound operation. If β_1 is $\{\langle \oplus = \oplus x_1 + \oplus x_2, \texttt{One}\rangle\}$ and β_2 is $\{\langle \oplus = \oplus x_1 + \ominus x_2, \texttt{One}\rangle\}$, both $\beta_3 = \{\langle \oplus = \oplus x_1 + \oplus x_2, \texttt{ZeroOrOne}\rangle, \langle \oplus = \oplus x_1 + \ominus x_2, \texttt{ZeroOrOne}\rangle\}$ and $\beta_4 = \{\langle \oplus = \oplus x_1 + \top x_2, \texttt{One}\rangle\}$ are upper bounds of β_1 and β_2 but they are incomparable. This problem cannot be avoided and indicates the inherent tradeoff between the accuracy of the signs and the accuracy of the multiplicity. In practice, one should choose an upper bound appropriate to the application at hand. For this reason, we design a general scheme to generate upper bound operations. Any operation built along the scheme is an upper bound. We use the notation $\gamma :: \beta$ to denote the set $\{\gamma\} \cup \beta$ with $\gamma \notin \beta$.

Implementation 2 (*Upper bound on abstract stores*). An upper bound operation on abstract stores UNION: $AS_D \times AS_D \to AS_D$ is any operation obtained by applying in a nondeterministic way the following set of rules.

1] $\texttt{UNION}(\emptyset, \emptyset) = \emptyset$,
2(i)] $\texttt{UNION}(\langle \sigma, \texttt{One}\rangle :: \beta_1', \beta_2) = \texttt{UNION}(\beta_1', \beta_2) \uplus \langle \sigma, \texttt{ZeroOrOne}\rangle$,
(ii)] $\texttt{UNION}(\beta_1, \langle \sigma, \texttt{One}\rangle :: \beta_2') = \texttt{UNION}(\beta_1, \beta_2') \uplus \langle \sigma, \texttt{ZeroOrOne}\rangle$,
3(i)] $\texttt{UNION}(\langle \sigma, \mu\rangle :: \beta_1', \beta_2) = \texttt{UNION}(\beta_1', \beta_2) \uplus \langle \sigma, \mu\rangle$ if $\mu \neq \texttt{One}$,
(ii)] $\texttt{UNION}(\beta_1, \langle \sigma, \mu\rangle :: \beta_2') = \texttt{UNION}(\beta_1, \beta_2') \uplus \langle \sigma, \mu\rangle$ if $\mu \neq \texttt{One}$,
4] $\texttt{UNION}(\langle s_0 \delta \sum_{i=1}^n s_i x_i, \mu\rangle :: \beta_1', \langle s_0' \delta \sum_{i=1}^n s_i' x_i, \mu'\rangle :: \beta_2') =$
$\texttt{UNION}(\beta_1', \beta_2') \uplus \langle (s_0 \sqcup s_0') \delta \sum_{i=1}^n (s_i \sqcup s_i') x_i, \mu \sqcup \mu'\rangle\rangle$

Rules 2i and 2ii trade the precision of the multiplicity information for the precision of the coefficients, since the constraint is no longer required but its coefficients remain the same. Rules 3i and 3ii do not lose information. Rule 4 trades the precision of the coefficients for the precision of the multiplicity. It is appropriate whenever μ and μ' are not Any, since they preserve the information that at most one constraint (or possibly exactly one) is represented.

Example 4.9. Given the abstract stores $\{\langle 0 = \oplus\texttt{T}, \texttt{One}\rangle\}$ and $\{\langle \oplus = \oplus\texttt{T}, \texttt{One}\rangle, \langle 0 < \oplus\texttt{T}, \texttt{One}\rangle\}$, both $\{\langle 0 = \oplus\texttt{T}, \texttt{ZeroOrOne}\rangle, \langle \oplus = \oplus\texttt{T}, \texttt{ZeroOrOne}\rangle, \langle 0 < \oplus\texttt{T}, \texttt{ZeroOrOne}\rangle\}$ (applying rule 2 thrice) and $\{\langle \top = \oplus\texttt{T}, \texttt{One}\rangle, \langle 0 < \oplus\texttt{T}, \texttt{ZeroOrOne}\rangle\}$ (applying rules 4 and 2) are upper bounds.

The following theorem states that the implementation of the upper bound operation satisfies its specification.

Theorem 4.6. *Let β_1 and β_2 be abstract stores and θ be a constraint store.*
(i) $\theta \in Cc_i(\beta_1) \vee \theta \in Cc_i(\beta_2) \Rightarrow \theta \in Cc_i(\texttt{UNION}(\beta_1, \beta_2))$.
(ii) $\theta \in Cc(\beta_1) \vee \theta \in Cc(\beta_2) \Rightarrow \theta \in Cc(\texttt{UNION}(\beta_1, \beta_2))$.

We now turn to the *projection of a contraint store.* Fig. 1 describes a simple projection algorithm based on the traditional Gaussian and Fourier eliminations which

```
Cproject_set(θ, V) {
if V = ∅ return θ;
else let V = {v} ∪ V' ∧ v ∉ V' in
   return Cproject_set(Cproject(θ, v), V');
}

Cproject(θ, v) {
if θ = ∅ return ∅;
else let θ = {λ} ⊎ θ' in
   case op(λ) is '=' ∧ λ[v] > 0 :
      return Cgauss(θ',λ,v);
   case op(λ) is '=' ∧ λ[v] < 0 :
      return Cgauss(θ',Cneg(λ),v);
   otherwise:
      return Cfourier(θ, v);
}

Cgauss(θ,λ, v) {
if θ = ∅ return ∅;
else let θ = {λ'} ⊎ θ' in
   return Cgauss(θ',λ,v) ⊎
          {Celiminate(λ',λ,v)};
}

Cfourier(θ, v) {
if θ = ∅ return ∅;
else let θ = {λ}⊎θ' in
   ⟨θ1^0, θ1^+, θ1^-⟩ := Csplit({λ}, v);
   ⟨θ2^0, θ2^+, θ2^-⟩ := Csplit(θ', v);
   return θ1^0 ⊎ Cfourier_step(θ1^+,θ2^-,v)
               ⊎ Cfourier_step(θ2^+,θ1^-,v)
               ⊎ Cfourier(θ',v);
}

Cfourier_step(θ^+,θ^-,v) {
θ := ∅;
for each λ^+ ∈ θ^+ and λ^- ∈ θ^-
   θ := θ ⊎ {Ccombine(λ^-,λ^+,v)};
return θ;
}

Csplit(θ, v) {
return Csplit_basic(θ, v)
}
```

```
Cneg(λ) {
for i = 0, ..., n
   λ'[i] := - λ[i];
op(λ') := '=';
return λ';
}

Celiminate(λ1,λ=^±,v) {
for i := 0, ..., n
   λ[i] := λ=^±[v] × λ1[i] − λ1[v] × λ=^±[i];
λ[v] := 0;
op(λ) := op(λ1);
return λ;
}

Ccombine(λ^-,λ^+,v) {
for i := 0, ..., n
   λ[i] := λ^+[v] × λ^-[i] − λ^-[v] × λ^+[i];
λ[v] := 0;
op(λ) := op(λ^-) ⋈ op(λ^+);
return λ;
}
```

⋈	<	≤	=

Fig. 2. Abstract projection algorithms.

are standard in this area. Fig. 2 presents the abstract algorithm. The algorithms are close to those in Ref. [28] but they are simplified thanks to the introduction of operations `Csplit` and `Asplit` which avoids much of the tedious case analysis. The algorithms are also more precise.

The intuition behind the concrete version is as follows. `Cproject` nondeterministically chooses a constraint in the store. If the constraint is an equation whose coefficient for x_v is non-zero, Gaussian elimination is performed. Otherwise, Fourier elimination is used. Gaussian elimination uses the equation or its negation to eliminate x_v from each of the other constraints in the store. The elimination is achieved by applying `Celiminate` on a pair of constraints. Fourier elimination considers each constraint in turn, partitions the store once again, and uses Fourier elimination on the compatible pairs.

The abstract version mimics almost line by line the concrete version showing the benefits of using operations `Csplit` and `Asplit`. The only place where we deal with $\top$ is precisely in `Asplit_top`, which is used in the abstract version in order to simplify the handling of $\top$ coefficients in Fourier elimination. Before eliminating variable x_v through Fourier elimination, `Asplit_top` is used to change the $\top$ coefficients of x_v in the store to $0, \oplus$ or $\ominus$.

`CSplit_basic` and `ASplit_basic` split a (concrete or abstract) store into three partitions with the coefficient of x_v positive, negative, or zero. Operation `Csplit` partitions the store into three sets depending upon the coefficient of x_v. Its abstract version needs to deal with the case where the coefficient of the abstract constraint is $\top$. This is handled in `Asplit_top` whereby, `Asplit_basic` mimics `Csplit_basic` almost line by line. Similarly, operation `Afourier` closely mimics operation `Cfourier`. The main difference comes from the fact that we avoid combining a constraint with multiplicity `One` or `ZeroOrOne` with itself, contrary to the algorithm in Ref. [28]. This is achieved by testing the multiplicity of the constraint.

Of course, in the abstract algorithm, operations and relations on signs replace operations and relations on coefficients. We need to assume operations like $+, -, \times$ on signs; these operations must be consistent approximations of the corresponding operations on $\Re$. For instance, $c_1 \in Cc(s_1) \wedge c_2 \in Cc(s_2) \Rightarrow c_1 + c_2 \in Cc(s_1 + s_2)$. Operations `Aneg`, `Aeliminate`, and `Acombine` mimic `Cneg`, `Celiminate`, and `Ccombine` respectively, by performing operations on signs instead of on coefficients. Operation `Agauss` mimics operation `Cgauss` line by line. Contrary to the algorithm in Ref. [28], the abstract Gaussian elimination algorithm does not split the $\top$ coefficients of the variable being eliminated into 0, $\oplus$ and $\ominus$. This enables it to be more precise in some cases.

Example 4.10. Let $\gamma_1 = \langle 0 \leqslant \oplus \mathtt{R} + \oplus \mathtt{B}, \mathtt{One} \rangle$, $\gamma_2 = \langle 0 = \oplus \mathtt{P} + \top \mathtt{R} + \ominus \mathtt{B}, \mathtt{One} \rangle$ and $\beta = \{\gamma_1, \gamma_2\}$. Then

$$\mathtt{Asplit}(\{\gamma_1\}, \mathtt{R}) = \langle \beta_1^0, \beta_1^+, \beta_1^- \rangle = \langle \emptyset, \{\langle 0 \leqslant \oplus \mathtt{R} + \oplus \mathtt{B}, \mathtt{One} \rangle\}, \emptyset \rangle,$$

$$\begin{aligned} \mathtt{Asplit}(\{\gamma_2\}, \mathtt{R}) = \langle \beta_2^0, \beta_2^+, \beta_2^- \rangle = \langle & \{\langle 0 = \oplus \mathtt{P} + \ominus \mathtt{B}, \mathtt{ZeroOrOne} \rangle\}, \\ & \{\langle 0 = \oplus \mathtt{P} + \oplus \mathtt{R} + \ominus \mathtt{B}, \mathtt{ZeroOrOne} \rangle\}, \\ & \{\langle 0 = \oplus \mathtt{P} + \ominus \mathtt{R} + \ominus \mathtt{B}, \mathtt{ZeroOrOne} \rangle\} \rangle. \end{aligned}$$

According to the algorithm,

$$\begin{aligned}\texttt{Afourier}(\beta,\texttt{R}) &= \beta_1^0 \biguplus \texttt{Afourier\_step}(\beta_1^+,\beta_2^-,\texttt{R}) \biguplus \\ &\quad \texttt{Afourier\_step}(\beta_2^+,\beta_1^-,\texttt{R}) \biguplus \texttt{Afourier}(\{\gamma_2\},\texttt{R}) \\ &= \emptyset \biguplus \{\langle 0 \leqslant \oplus\texttt{P} + \top\texttt{B}, \texttt{ZeroOrOne}\rangle\} \biguplus \\ &\quad \emptyset \biguplus \texttt{Afourier}(\{\gamma_2\},\texttt{R}).\end{aligned}$$

By similar reasoning, we have that

$$\texttt{Afourier}(\{\gamma_2\},\texttt{R}) = \{\langle 0 = \oplus\texttt{P} + \ominus\texttt{B}, \texttt{ZeroOrOne}\rangle\}.$$

This gives

$$\texttt{Afourier}(\beta,\texttt{R}) = \{\langle 0 \leqslant \oplus\texttt{P} + \top\texttt{B}, \texttt{ZeroOrOne}\rangle, \langle 0 = \oplus\texttt{P} + \ominus\texttt{B}, \texttt{ZeroOrOne}\rangle\}.$$

Finally, `Cproject_set` and `Aproject_set` merely extend the projection operation to project a set of variables from a store, rather than just one variable. The correctness proofs of the operations above can be found in Ref. [36].

Theorem 4.7 (Project). *Let $v \in \mathscr{I}$, θ be a store and β be an abstract store.*

$$\theta \in Cc(\beta) \;\Rightarrow\; \texttt{Cproject}(\theta, v) \in Cc(\texttt{Aproject}(\beta, v)).$$

Corollary 4.1 (Project set). *Let $V \in 2^{\mathscr{I}}$, θ be a store and β be an abstract store.*

$$\theta \in Cc(\beta) \;\Rightarrow\; \texttt{Cproject\_set}(\theta, V) \in Cc(\texttt{Aproject\_set}(\beta, V)).$$

Discussion. It is interesting to discuss some of our improvements over [28]. The first improvement is on the accuracy of abstract Fourier elimination. In Ref. [28], when Fourier eliminating x from a constraint that contains x with coefficient $\top$, that constraint is always combined with itself (as it may represent two concrete constraints with opposite coefficients for x). This is avoided in our domain by explicitly checking the multiplicity of the constraint and combining it with itself only if its multiplicity is `Any`. For example, projecting x from $\{\langle \top = \top x + \oplus y, \texttt{ZeroOrOne}\rangle\}$ leads to the store $\{\langle \top = \oplus y, \texttt{ZeroOrOne}\rangle, \langle \top = \oplus y, \texttt{Any}\rangle\}$ using the algorithm of [28]. The first abstract constraint in this store comes from taking the $\top$ coefficient of x to be 0, while the second constraint comes from taking the $\top$ coefficient of x to be $\oplus$ and $\ominus$ and combining the two. This store cannot be deduced to be definitely satisfiable by projecting y as it potentially contains more than one different assignment of a value to y. Our improved algorithm would lead to the store $\{\langle \top = \oplus y, \texttt{ZeroOrOne}\rangle\}$, which can be easily seen to be definitely satisfiable.

The second improvement is on the accuracy of abstract Gauss elimination. Consider the following example. Using the algorithms of Ref. [28], projecting x from $\{\langle \oplus = \oplus x, \texttt{One}\rangle, \langle \top = \top x + \oplus y, \texttt{One}\rangle\}$ involves considering the cases 0, $\oplus$ and $\ominus$ for the $\top$ coefficient of x in the second constraint, leading to $\{\langle \top = \oplus y, \texttt{ZeroOrOne}\rangle, \langle \top = \oplus y, \texttt{Any}\rangle\}$ which may or may not be satisfiable. However, by directly substituting $\langle \oplus = \oplus x, \texttt{One}\rangle$ into the second constraint, we get a simpler abstract store $\{\langle \top = \oplus y, \texttt{One}\rangle\}$ that accurately describes the result of projecting x and which can be deduced to be definitely satisfiable. Our abstract Gauss elimination algorithm produces the above store by avoiding the imprecise splitting of the coefficient $\top$.

4.3. Satisfiability

Reordering algorithms for CLP programs [36] are based on one fundamental operation: testing if a constraint store $\theta_1 \cup \theta_2$ is satisfiable whenever θ_1 is satisfiable. This operation makes it possible to determine if a constraint can prune the search space in a goal. This section discusses how to use LSign for abstracting this operation.

Consider first the problem of *determining whether a constraint store is satisfiable.* In the concrete domain, this problem can be formalized by a function Cis_sat : $CS_D \rightarrow$ Boolean which takes a constraint store θ and returns a Boolean value which is true if θ is satisfiable and false otherwise. An implementation of Cis_sat is given in Fig. 3. It consists of the well known technique of projecting all the variables from the store and checking if the resulting ground constraints (i.e. constraints with zero coefficients for all variables) are all trivially satisfiable. Its abstract counterpart Ais_sat, also given in Fig. 3, makes a conservative approximation to Cis_sat.

Theorem 4.8 (Is satisfiable). *Let θ be a store and β be an abstract store.* $\theta \in Cc(\beta) \Rightarrow (\texttt{Ais\_sat}(\beta) \Rightarrow \texttt{Cis\_sat}(\theta))$.

Example 4.11. Projecting all the variables from $\{0 \leqslant \mathtt{R} + \mathtt{B},\ 0 = \mathtt{B},\ 3 = \mathtt{R}\}$ gives the constraint store $\{-3 \leqslant 0\}$, indicating that the original constraint store is satisfiable.

Projecting all the variables from $\{\langle 0 \leqslant \oplus \mathtt{R} + \oplus \mathtt{B},\ \mathtt{One}\rangle,\ \langle 0 = \oplus \mathtt{B},\ \mathtt{One}\rangle,\ \langle \oplus = \oplus \mathtt{R},\ \mathtt{One}\rangle\}$ gives the abstract store $\{\langle \ominus \leqslant 0,\ \mathtt{One}\rangle\}$, indicating that all the constraint stores in its concretization are satisfiable.

Projecting all the variables from $\{\langle \top \leqslant \oplus \mathtt{R} + \oplus \mathtt{B},\ \mathtt{One}\rangle,\ \langle 0 = \oplus \mathtt{B},\ \mathtt{One}\rangle,\ \langle \oplus = \oplus \mathtt{R},\ \mathtt{One}\rangle\}$ gives the abstract store $\{\langle \top \leqslant 0,\ \mathtt{One}\rangle\}$, indicating that some of the constraint stores in its concretization *may not* be satisfiable.

Consider now the problem of *determining whether a constraint store is unsatisfiable.* In the concrete domain, this problem can be formalized by the function Cis_unsat : $CS_D \rightarrow$ Boolean which takes a constraint store θ and returns a Boolean

```
Cis_sat(θ) {
θ_p = Cproject_set(θ, I);
return Cis_triv_sat(θ_p);
}

Cis_triv_sat(θ) {
if θ = ∅ return true ;
else let θ = {λ} ∪ θ' in
    case λ is c0 < Σ_{i=1}^{n} 0x_i ∧ c0 < 0:
    case λ is c0 = Σ_{i=1}^{n} 0x_i ∧ c0 = 0:
    case λ is c0 ≤ Σ_{i=1}^{n} 0x_i ∧ c0 ≤ 0:
        return Cis_triv_sat(θ');
    otherwise:
        return false;
}
```

```
Ais_sat(β) {
β_p = Aproject_set(β, I);
return Ais_triv_sat(β_p);
}

Ais_triv_sat(β) {
if β = ∅ return true ;
else let β = {γ} ∪ β' ∧ γ = ⟨σ, μ⟩ ∉ β' in
    case σ is s0 < Σ_{i=1}^{n} 0x_i ∧ s0 = ⊖:
    case σ is s0 = Σ_{i=1}^{n} 0x_i ∧ s0 = 0:
    case σ is s0 ≤ Σ_{i=1}^{n} 0x_i ∧ (s0 = 0 ∨ s0 = ⊖):
        return Ais_triv_sat(β');
    otherwise:
        return false;
}
```

Fig. 3. Satisfiability algorithms.

```
Cis_unsat(θ) {
θ_p = Cproject_set(θ, I);
return Cis_triv_unsat(θ_p);
}

Cis_triv_unsat(θ) {
if θ = ∅ return true ;
else let θ = {λ} ⊎ θ' in
    case λ is c_0 < Σ_{i=1}^{n} 0x_i ∧ c_0 ≥ 0:
    case λ is c_0 = Σ_{i=1}^{n} 0x_i ∧ c_0 ≠ 0:
    case λ is c_0 ≤ Σ_{i=1}^{n} 0x_i ∧ c_0 > 0:
        return true;
    otherwise:
        return Cis_triv_unsat(θ');
}

Ais_unsat(β) {
β_p = Aproject_set(β, I);
return Ais_triv_unsat(β_p);
}

Ais_triv_unsat(β) {
if β = ∅ return true ;
else let β = {γ} ⊎ β' ∧ γ = ⟨σ, μ⟩ ∉ β' in
    case σ is s_0 < Σ_{i=1}^{n} 0x_i ∧ (s_0 = 0 ∨ s_0 = ⊕)
            ∧ μ = One:
    case σ is s_0 = Σ_{i=1}^{n} 0x_i ∧ (s_0 = ⊕ ∨ s_0 = ⊖)
            ∧ μ = One:
    case σ is s_0 ≤ Σ_{i=1}^{n} 0x_i ∧ s_0 = ⊕
            ∧ μ = One:
        return true;
    otherwise:
        return Ais_triv_unsat(β');
}
```

Fig. 4. Unsatisfiability algorithms.

value which is true if θ is unsatisfiable and false otherwise. The function `Cis_unsat` is exactly the logical negation of the function `Cis_sat`. The definition of `Cis_unsat` (Fig. 4) is defined by projecting all the variables from the store and checking if any of the resulting ground constraints (i.e. constraints with zero coefficients for all variables) is trivially unsatisfiable. Its abstract counterpart `Ais_unsat`, also given in Fig. 4, makes a conservative approximation to `Cis_unsat`.

Theorem 4.9 (Is unsatisfiable). *Let θ be a store and β be an abstract store.* $\theta \in Cc(\beta) \Rightarrow (\texttt{Ais\_unsat}(\beta) \Rightarrow \texttt{Cis\_unsat}(\theta))$.

Note that `Ais_unsat` is not the logical negation of `Ais_sat`, unlike in the concrete domain.

Example 4.12. Projecting all the variables from $\{0 \leqslant \mathtt{R} + \mathtt{B},\ 0 = \mathtt{B},\ -3 = \mathtt{R}\}$ gives the constraint store $\{3 \leqslant 0\}$, indicating that the original constraint store is unsatisfiable.

Projecting all the variables from $\{\langle 0 \leqslant \oplus\mathtt{R} + \oplus\mathtt{B},\ \mathtt{One}\rangle,\ \langle 0 = \oplus\mathtt{B},\ \mathtt{One}\rangle,\ \langle \ominus = \oplus\mathtt{R},\ \mathtt{One}\rangle\}$ gives the abstract store $\{\langle \oplus \leqslant 0,\ \mathtt{One}\rangle\}$, indicating that all the constraint stores in its concretization are unsatisfiable.

Projecting all the variables from $\{\langle \top \leqslant \oplus\mathtt{R} + \oplus\mathtt{B},\ \mathtt{One}\rangle,\ \langle 0 = \oplus\mathtt{B},\ \mathtt{One}\rangle,\ \langle \oplus = \oplus\mathtt{R},\ \mathtt{One}\rangle\}$ gives the abstract store $\{\langle \top \leqslant 0,\ \mathtt{One}\rangle\}$, indicating that some of the constraint stores in its concretization *may not* be unsatisfiable.

Finally, consider the problem of *conditional satisfiability of constraint stores.* In the concrete domain, this problem can be formalized by the function $\texttt{Cis\_cond\_sat} : CS_D \times CS_D \rightarrow$ Boolean which takes two constraint stores θ_1 and θ_2 and returns true if the conjunction $\theta_1 \uplus \theta_2$ is satisfiable whenever θ_1 is satisfiable. In other words,

$$\begin{aligned}\texttt{Cis\_cond\_sat}(\theta_1,\theta_2) &= \texttt{Cis\_sat}(\theta_1) \Rightarrow \texttt{Cis\_sat}(\theta_1 \underline{\cup} \theta_2)\\ &= \texttt{Cis\_unsat}(\theta_1) \ \vee \ \texttt{Cis\_sat}(\theta_1 \underline{\cup} \theta_2).\end{aligned}$$

The need for such an operation arises when it is necessary to verify that adding any constraint store in the concretization of β_2 to any satisfiable constraint store in the concretization of β_1 does not cause the resulting constraint store to become unsatisfiable. The operation is the cornerstone of the analysis for reordering constraints in $\texttt{CLP}(\mathfrak{R}_{Lin})$ programs. While the definition of Cis_cond_sat is straightforward, it does not lend itself to a straightforward satisfactory abstraction. A naive implementation of Ais_cond_sat is

$$\texttt{Ais\_cond\_sat}(\beta_1,\beta_2) = \texttt{Ais\_unsat}(\beta_1) \ \vee \ \texttt{Ais\_sat}\left(\beta_1 \underline{\uplus} \beta_2\right).$$

However, this naive implementation is not sufficiently accurate in practice because the operations Ais_sat and Ais_unsat are not logical negations of one another. It becomes necessary to transform the store β_1 to remove sources of unsatisfiability in β_1 before checking the satisfiability of $\beta_1 \underline{\uplus} \beta_2$. More formally, we are looking forward an implementation like

$$\texttt{Ais\_cond\_sat}(\beta_1,\beta_2) = \texttt{Ais\_unsat}(\beta_1) \ \vee \ \texttt{Ais\_sat}\left(\beta' \underline{\uplus} \beta_2\right),$$

where β' is an abstract description of $\{\theta \in Cc(\beta_1) \mid \texttt{Cis\_sat}(\theta)\}$ as accurate as possible. At this aim, we introduce four transformations to remove possible sources of unsatisfiability. Two of these, i.e., eliminating with equations and projecting irrelevant variables, serve to make the information available on the constraint store more explicit. The third, i.e., reducing top coefficients, corresponds to making the signs of the abstract store more accurate. It is to be performed before eliminating with equations so that the sign information in inequalities is not lost. The final transformation, i.e., removing ground constraints is to be applied last as the previous transformations may introduce ground constraints.

Removing ground constraints. In the concrete domain, the transformation Cred_gnd (Fig. 5) removes all ground constraints (i.e. constraints with zero coefficients for all variables) from a constraint store, and it is an equivalence transformation for satisfiable constraint stores.

Proposition 4.1. *Let θ be a constraint store. Then θ satisfiable $\Rightarrow$ $(\theta \leftrightarrow \texttt{Cred\_gnd}(\theta))$.*

While Cred_gnd is not a very useful transformation for constraint stores, the following example indicates why its abstraction Ared_gnd (given in Fig. 5) is important to improve the accuracy of conditional satisfiability in the abstract domain.

Example 4.13. Let $\beta_1 = \{\langle \top = \oplus\texttt{X}, \texttt{One}\rangle, \langle \top < 0, \texttt{One}\rangle\}$ and $\beta_2 = \{\langle 0 = \oplus\texttt{X} + \oplus\texttt{Y}, \texttt{One}\rangle$. Because β_2 only represents stores that have a simple linear relation between X and Y, and β_1 represents stores that do not involve Y at all, it can be seen that for any satisfiable constraint store $\theta_1 \in Cc(\beta_1)$ and constraint store $\theta_2 \in Cc(\beta_2)$, we have that $\texttt{Cis\_sat}(\theta_1 \underline{\cup} \theta_2)$ is true. We expect therefore that Ais_cond_sat (β_1,β_2) returns true. However we see that

```
Creduce(θ) {
return Cred_gnd(Cred_eqn(θ));
}

Cred_gnd(θ) {
if θ = ∅ return ∅;
else let θ = {λ} ⊔ θ' in
    case λ is c0 δ Σ_{i=1}^{n} 0x_i:
        return Cred_gnd(θ');
    otherwise:
        return Cred_gnd(θ') ⊔ {λ};
}

Cred_eqn(θ) {
return Cred_eqn_set(θ, I);
}

Cred_eqn_set(θ, V) {
if V = ∅ return θ;
else let V = {v} ∪ V' ∧ v ∉ V' in
    θ_v := Cred_eqn_step(θ, v);
    return Cred_eqn_set(θ_v, V');
}

Cred_eqn_step(θ, v) {
if θ = ∅ return ∅;
else let θ = {λ} ⊔ θ' in
    case op(λ) is '=' ∧ λ[v] > 0:
        return Cgauss(θ',λ,v) ⊔ {λ};
    case op(λ) is '=' ∧ λ[v] < 0:
        return Cgauss(θ',Cneg(λ),v) ⊔ {λ};
    otherwise:
        return θ;
}
```

```
Areduce(β) {
return Ared_gnd(Ared_eqn(Ared_top(β)));
}

Ared_gnd(β) {
if β = ∅ return ∅;
else let β = {γ} ⊔ β' ∧ γ = ⟨σ, μ⟩ ∉ β' in
    case σ is s0 δ Σ_{i=1}^{n} 0x_i:
        return Ared_gnd(β');
    otherwise:
        return Ared_gnd(β') ⊎ γ;
}

Ared_eqn(β) {
return Ared_eqn_set(β, I);
}

Ared_eqn_set(β, V) {
if V = ∅ return β;
else let V = {v} ∪ V' ∧ v ∉ V' in
    β_v := Ared_eqn_step(β, v);
    return Ared_eqn_set(β_v, V');
}

Ared_eqn_step(β, v) {
if β = ∅ return ∅;
else let β = {γ} ⊔ β' ∧ γ = ⟨σ, μ⟩ ∉ β' in
    case μ = One ∧ op(σ) is '=' ∧ σ[v] = ⊕:
        return Agauss(β',σ,v) ⊎ γ;
    case μ = One ∧ op(σ) is '=' ∧ σ[v] = ⊖:
        return Agauss(β',Aneg(σ),v) ⊎ γ;
    otherwise:
        return β;
}
```

```
Ared_top(β) {
if β = ∅ return ∅;
else if |β| = 1 return β;
else let β = {γ1, γ2} ⊔ β' ∧ γ1 = ⟨σ1, μ1⟩ ∉ β' ∧ γ2 = ⟨σ2, μ2⟩ ∉ β' in
    case μ1 = One ∧ (σ1 is ⊕ ≤ ⊕x_v ∨ σ1 is 0 < ⊕x_v ∨ σ1 is ⊕ < ⊕x_v)
        ∧(σ2 is ⊤ = ⊕x_v ∨ σ2 is ⊤ = ⊖x_v):
        return Ared_top(β' ⊎ γ1) ⊎ ⟨⊕ = ⊕x_v, μ2⟩;
    case μ1 = One ∧ (σ1 is ⊕ ≤ ⊖x_v ∨ σ1 is 0 < ⊖x_v ∨ σ1 is ⊕ < ⊖x_v)
        ∧(σ2 is ⊤ = ⊕x_v ∨ σ2 is ⊤ = ⊖x_v):
        return Ared_top(β' ⊎ γ1) ⊎ ⟨⊖ = ⊕x_v, μ2⟩;
    otherwise:
        return β;
}
```

Fig. 5. Reduction algorithms.

$$\begin{aligned}\texttt{Ais\_cond\_sat}(\beta_1,\beta_2) &= \texttt{Ais\_unsat}(\beta_1) \ \vee \ \texttt{Ais\_sat}\left(\beta_1 \biguplus \beta_2\right)\\ &= \text{false} \ \vee \ \texttt{Ais\_triv\_sat}(\{\langle \top < 0, \texttt{One}\rangle\})\\ &= \text{false}.\end{aligned}$$

This inaccuracy arises because of the possibly unsatisfiable ground constraint $\langle \top < 0, \texttt{One} \rangle$ in β_1. However, there is another abstract store $\beta_1' = \{\langle \top = \oplus X, \texttt{One} \rangle\}$ which includes all the satisfiable constraint stores of $Cc(\beta_1)$ in its concretization and such that $\texttt{Ais\_sat}(\beta_1' \biguplus \beta_2)$ is true. Moreover, $\beta_1' = \texttt{Ared\_gnd}(\beta_1)$.

An improved implementation of Ais_cond_sat, may therefore be given by

$$\texttt{Ais\_cond\_sat}(\beta_1, \beta_2) = \texttt{Ais\_unsat}(\beta_1) \ \vee \ \texttt{Ais\_sat}\Big(\texttt{Ared\_gnd}(\beta_1) \biguplus \beta_2\Big).$$

Eliminating equations. In the concrete domain, the transformation Cred_eqn (Fig. 5) looks for an equation for each variable and, if possible, uses the equation to eliminate the variable from the rest of the store (operation Cred_eqn_step). This corresponds to substituting the value of the variable in the rest of the store, but not removing the equation used to perform the substitution. Cred_eqn is an equivalence transformation on stores, i.e., the following proposition holds.

Proposition 4.2. *Let $v \in \mathscr{I}, V \in 2^{\mathscr{I}}$ and θ be a store. Then*

$$\theta \leftrightarrow \texttt{Cred\_eqn\_step}(\theta, v) \leftrightarrow \texttt{Cred\_eqn\_set}(\theta, V) \leftrightarrow \texttt{Cred\_eqn}(\theta).$$

The following example indicates why the abstraction of Cred_eqn, i.e. Ared_eqn (given in Fig. 5) is important for the accuracy of conditional satisfiability.

Example 4.14. Let $\beta_1 = \{\langle \oplus = \oplus X, \texttt{One} \rangle, \langle \top < \oplus X, \texttt{One} \rangle\}$ and $\beta_2 = \{\langle 0 = \oplus X + \oplus Y, \texttt{One} \rangle\}$. For any satisfiable constraint stores $\theta_1 \in Cc(\beta_1)$ and $\theta_2 \in Cc(\beta_2)$, we have that $\texttt{Cis\_sat}(\theta_1 \cup \theta_2)$ is true. However we see that

$$\begin{aligned}
\texttt{Ais_cond_sat}(\beta_1, \beta_2) &= \texttt{Ais_unsat}(\beta_1) \ \vee \ \texttt{Ais_sat}\Big(\beta_1 \biguplus \beta_2\Big) \\
&= \text{false} \ \vee \ \texttt{Ais_triv_sat}(\{\langle \top < 0, \texttt{One} \rangle\}) \\
&= \text{false}.
\end{aligned}$$

This inaccuracy arises because the two abstract constraints in β_1 may be potentially unsatisfiable together (combining to produce $\top < 0$). It can be observed however that there is another abstract store $\beta_1' = \{\langle \oplus = \oplus X, \texttt{One} \rangle\}$ which includes all the satisfiable constraint stores of $Cc(\beta_1)$ in its concretization (under equivalence closure) and such that $\texttt{Ais\_sat}(\beta_1' \biguplus \beta_2)$ is true. Moreover, $\beta_1' = \texttt{Ared\_gnd}(\texttt{Ared\_eqn}(\beta_1))$.

It is important to first use the equations to simplify the store and then use Ared_gnd to remove ground constraints. This is because Ared_eqn may introduce ground constraints when it eliminates with equations. An improved implementation of Ais_cond_sat, may therefore be given as

$$\begin{aligned}
\texttt{Ais_cond_sat}(\beta_1, \beta_2) = \ & \texttt{Ais_unsat}(\beta_1) \\
& \vee \ \texttt{Ais_sat}(\texttt{Ared_gnd}\Big(\texttt{Ared_eqn}(\beta_1)) \biguplus \beta_2\Big).
\end{aligned}$$

Reducing top coefficients. The third transformation does not have any counterpart in the concrete domain. It consists of reducing the number of top coefficients in the abstract store β_1 so as to improve its accuracy. The following example motivates the transformation.

Example 4.15. Let $\beta_1 = \{\langle \top = \oplus X, \texttt{One}\rangle, \langle 0 < \oplus X, \texttt{One}\rangle\}$ and $\beta_2 = \{\langle 0 = \oplus X + \oplus Y, \texttt{One}\rangle\}$. Again it can be seen that for any satisfiable constraint store $\theta_1 \in Cc(\beta_1)$ and constraint store $\theta_2 \in Cc(\beta_2)$, we have that $\texttt{Cis\_sat}(\theta_1 \underline{\cup} \theta_2)$ is true. However we see that

$$\begin{aligned}\texttt{Ais\_cond\_sat}(\beta_1, \beta_2) &= \texttt{Ais\_unsat}(\beta_1) \ \vee \ \texttt{Ais\_sat}\Big(\beta_1 \biguplus \beta_2\Big),\\ &= \text{false} \ \vee \ \texttt{Ais\_triv\_sat}(\{\langle \top < 0, \texttt{One}\rangle\}),\\ &= \text{false}.\end{aligned}$$

This inaccuracy arises because of the top coefficient in β_1. It can be observed that there is another abstract store $\beta_1' = \{\langle \oplus = \oplus X, \texttt{One}\rangle, \langle 0 < \oplus X, \texttt{One}\rangle\}$ which includes all the satisfiable constraint stores of $Cc(\beta_1)$ in its concretization and such that $\texttt{Ais\_sat}\big(\beta_1' \biguplus \beta_2\big)$ is true.

The basic idea is to consider the cases 0, $\oplus$ and $\ominus$ for each $\top$ coefficient in the store β_1 and see if any two of them make the store unsatisfiable (using `Ais_unsat`). In that case, the $\top$ coefficient can be replaced by the third sign. To do this in general for a store would be a very expensive operation. We therefore present a more specific version of the transformation which captures most of the cases that occur in practice. The transformation `Ared_top` (Fig. 5) uses any inequality that restricts the sign of a variable, to refine any equation that assigns $\top$ to that variable. It is important to perform `Ared_top` before performing `Ared_eqn`, in order that any sign restricting inequality be used to make an equation more accurate before eliminating with that equation.

Reduction operation. The above transformations, aimed at removing unsatisfiable stores, can all be put together in a transformation called the definite satisfiability *reduction* (Fig. 5). The definition of `Areduce` retains all the satisfiable stores in the concretization, as stated by the following theorem.

Theorem 4.10 (Reduce). *Let θ be a store and β be an abstract store. Then*

$$\theta \in Cc(\beta) \ \wedge \ \theta \text{ satisfiable} \Rightarrow \theta \in Cc(\texttt{Areduce}(\beta)).$$

Using `Areduce`, the operation `Ais_cond_sat` can be implemented in a more accurate fashion as follows:

$$\texttt{Ais\_cond\_sat}(\beta_1, \beta_2) = \texttt{Ais\_unsat}(\beta_1) \ \vee \ \texttt{Ais\_sat}\Big(\texttt{Areduce}(\beta_1) \biguplus \beta_2\Big).$$

Projecting irrelevant variables. Even the above implementation of `Ais_cond_sat` is not sufficiently accurate, as can be seen by the following example.

Example 4.16. Let $\beta_1 = \{\langle \top < \top X, \texttt{One}\rangle\}$ and $\beta_2 = \{\langle 0 = \oplus X + \oplus Y, \texttt{One}\rangle\}$. It is obvious that for any satisfiable constraint store $\theta_1 \in Cc(\beta_1)$ and constraint store $\theta_2 \in Cc(\beta_2)$, we have that $\texttt{Cis\_sat}(\theta_1 \underline{\cup} \theta_2)$. We expect therefore that $\texttt{Ais\_cond\_sat}(\beta_1, \beta_2)$ returns true. However we see that

$$\begin{aligned}\texttt{Ais\_cond\_sat}(\beta_1, \beta_2) &= \texttt{Ais\_unsat}(\beta_1) \ \vee \ \texttt{Ais\_sat}\Big(\texttt{Areduce}(\beta_1) \biguplus \beta_2\Big),\\ &= \text{false} \ \vee \ \texttt{Ais\_triv\_sat}(\{\langle \top < 0, \texttt{ZeroOrOne}\rangle\}),\\ &= \text{false}.\end{aligned}$$

Intuitively, the inaccuracy is caused because β_1 contains unsatisfiable stores in its concretization, however the transformations performed by `Areduce` are not able to remove these unsatisfiable stores.

To understand how to overcome this limitation it is instructive to look at the concrete domain. If $\theta_1 \in Cc(\beta_1)$ and $\theta_2 \in Cc(\beta_2)$,

$$\begin{aligned}
&\texttt{Cis_sat}(\theta_1 \underline{\cup} \theta_2),\\
&= \texttt{Cis_triv_sat}(\texttt{Cproject_set}(\theta_1 \underline{\cup} \theta_2, \mathscr{I})),\\
&= \texttt{Cis_triv_sat}(\texttt{Cproject_set}(\texttt{Cproject_set}(\theta_1, \texttt{Var}(\theta_1) \setminus \texttt{Var}(\theta_2)) \underline{\cup} \theta_2, \mathscr{I})),\\
&= \texttt{Cis_sat}(\texttt{Cproject_set}(\theta_1, \texttt{Var}(\theta_1) \setminus \texttt{Var}(\theta_2)) \underline{\cup} \theta_2)
\end{aligned}$$

This suggests our final implementation for conditional satisfiability.

Definition 4.17 (*Is conditionally satisfiable*). The abstract conditional satisfiability operation $\texttt{Ais\_cond\_sat} : AS_D \times AS_D \rightarrow$ Boolean is given as

$$\begin{aligned}
&\texttt{Ais_cond_sat}(\beta_1, \beta_2), = \texttt{Ais_unsat}(\beta_1)\\
&\vee\ \texttt{Ais_sat}(\texttt{Areduce}(\texttt{Aproject_set}(\beta_1, \texttt{Var}(\beta_1) \setminus \texttt{Var}(\beta_2))) \underline{\uplus} \beta_2).
\end{aligned}$$

where $\texttt{Var}(\beta)$ is the set of variables of β that have a nonzero coefficient in β.

Note that `Areduce` is applied to β_1 after projecting the variables of β_1 that do not occur in β_2. This is because the projection may make explicit sources of inconsistency (eg. ground unsatisfiable constraints) that can then be removed by `Areduce`. The above implementation of conditional satisfiability satisfies its specification.

Theorem 4.11 (Conditional satisfiability). *Let θ_1, θ_2 be stores and β_1, β_2 be abstract stores. Then*

$$\begin{aligned}
&\theta_1 \in Cc(\beta_1)\ \wedge\ \theta_2 \in Cc(\beta_2)\\
&\quad \Rightarrow (\texttt{Ais_cond_sat}(\beta_1, \beta_2) \Rightarrow \texttt{Cis_cond_sat}(\theta_1, \theta_2)).
\end{aligned}$$

4.4. The power domain $2^{\texttt{LSign}}$

In practice, the `LSign` domain is not always sufficiently accurate to perform a practical analysis of CLP programs. In particular, the upper bound operation may lose too much information to be of practical use. It may therefore be necessary to move to the power domain $2^{\texttt{LSign}}$ in order to get the required accuracy. This is a fairly standard construction in abstract interpretation [12]. The technical details of this domain lifting can be found in Ref. [34]. Here, we show the computation of the goal independent (or online) output in the $2^{\texttt{LSign}}$ domain, for the mortgage program `mg/4` of Example, as it results by our prototype implementation.

Example 4.17 (*Computation of $2^{\texttt{LSign}}$ output description for* `mg/4`). The abstract substitution describing the output of the first clause is

$$\{\{\langle 0 = \oplus\texttt{T},\ \ \texttt{One}\rangle, \langle 0 = \oplus\texttt{P} + \ominus\texttt{B},\ \ \texttt{One}\rangle\}\}.$$

The abstract substitution describing the constraint store just before the recursive call in the second clause is

$$\{\{\langle 0 < \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle 0 \leqslant \oplus\,\mathtt{P},\ \mathtt{One}\rangle,\ \langle 0 = \oplus\mathtt{P} + \ominus\mathtt{R} + \ominus\mathtt{P1},\ \mathtt{One}\rangle,\ \langle \oplus = \oplus\mathtt{T} + \ominus\mathtt{T1},\ \mathtt{One}\rangle\}\}.$$

Extending this with the denormalized output of the recursive call (when the recursive call returns the previous output) gives the abstract substitution

$$\{\{\langle 0 < \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle 0 \leqslant \oplus\,\mathtt{P},\ \mathtt{One}\rangle,\ \langle 0 = \oplus\mathtt{P} + \ominus\mathtt{R} + \ominus\mathtt{P1},\ \mathtt{One}\rangle,\ \langle \oplus = \oplus\mathtt{T} + \ominus\mathtt{T1},\ \mathtt{One}\rangle,\ \langle 0 = \oplus\mathtt{T1},\ \mathtt{One}\rangle,\ \langle 0 = \oplus\mathtt{P1} + \ominus\mathtt{B},\ \mathtt{One}\rangle\}\}.$$

Restricting this to the head variables gives the following abstract substitution as the output of the second clause

$$\{\{\langle 0 < \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle \oplus = \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle 0 \leqslant \oplus\,\mathtt{P},\ \mathtt{One}\rangle,\ \langle 0 = \oplus\mathtt{P} + \ominus\mathtt{R} + \ominus\mathtt{B},\ \mathtt{One}\rangle\}\}.$$

The union of this with the previously computed output of the first clause[7] gives the following abstract substitution as the updated output of the predicate mg.

$$\{\{\langle 0 = \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle 0 = \oplus\mathtt{P} + \ominus\mathtt{B},\ \mathtt{One}\rangle\},\ \{\langle 0 < \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle \oplus = \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle 0 \leqslant \oplus\,\mathtt{P},\ \mathtt{One}\rangle,\ \langle 0 = \oplus\mathtt{P} + \ominus\mathtt{R} + \ominus\mathtt{B},\ \mathtt{One}\rangle\}\}.$$

This new output can be used as the output of the recursive call to mg, in order to recompute the output of the second clause of mg. This gives

$$\{\{\langle 0 < \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle 0 \leqslant \oplus\,\mathtt{P},\ \mathtt{One}\rangle,\ \langle 0 = \oplus\mathtt{P} + \ominus\mathtt{R} + \ominus\mathtt{P1},\ \mathtt{One}\rangle,\ \langle \oplus = \oplus\mathtt{T} + \ominus\mathtt{T1},\ \mathtt{One}\rangle\}\}$$

$$\biguplus$$

$$\{\{\langle 0 = \oplus\mathtt{T1},\ \mathtt{One}\rangle,\ \langle 0 = \oplus\mathtt{P1} + \ominus\mathtt{B},\ \mathtt{One}\rangle\},\ \{\langle 0 < \oplus\mathtt{T1},\ \mathtt{One}\rangle,\ \langle \oplus = \oplus\mathtt{T1},\ \mathtt{One}\rangle,\ \langle 0 \leqslant \oplus\,\mathtt{P1},\ \mathtt{One}\rangle,\ \langle 0 = \oplus\mathtt{P1} + \ominus\mathtt{R} + \ominus\mathtt{B},\ \mathtt{One}\rangle\}\}$$

for the program point after the recursive call. Restricting this to the head variables gives

$$\{\{\langle 0 < \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle \oplus = \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle 0 \leqslant \oplus\,\mathtt{P},\ \mathtt{One}\rangle,\ \langle 0 = \oplus\mathtt{P} + \ominus\mathtt{R} + \ominus\mathtt{B},\ \mathtt{One}\rangle\},\ \{\langle 0 < \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle \oplus = \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle 0 \leqslant \oplus\,\mathtt{P},\ \mathtt{One}\rangle,\ \langle 0 = \oplus\mathtt{P} + \ominus\mathtt{R} + \ominus\mathtt{B},\ \mathtt{One}\rangle,\ \langle 0 \leqslant \oplus\,\mathtt{R} + \oplus\mathtt{B},\ \mathtt{One}\rangle\}\}.$$

The union of this with the previously computed output of mg gives the updated output

$$\{\{\langle 0 = \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle 0 = \oplus\mathtt{P} + \ominus\mathtt{B},\ \mathtt{One}\rangle\},\ \{\langle 0 < \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle \oplus = \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle 0 \leqslant \oplus\,\mathtt{P},\ \mathtt{One}\rangle,\ \langle 0 = \oplus\mathtt{P} + \ominus\mathtt{R} + \ominus\mathtt{B},\ \mathtt{One}\rangle\},\ \{\langle 0 < \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle \oplus = \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle 0 \leqslant \oplus\,\mathtt{P},\ \mathtt{One}\rangle,\ \langle 0 = \oplus\mathtt{P} + \ominus\mathtt{R} + \ominus\mathtt{B},\ \mathtt{One}\rangle,\ \langle 0 \leqslant \oplus\,\mathtt{R} + \oplus\mathtt{B},\ \mathtt{One}\rangle\}\}.$$

The process can be repeated until it gives the following set of abstract store (multi-store) as the fixpoint for the computation of the output of mg.

[7] Of course, the analyser takes care of distinguishing "old" and "new" abstract equations, as usual in many abstract interpretation frameworks. See, for instance, Ref. [25] for a detailed discussion.

$$\{\{\langle 0 = \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle 0 = \oplus\mathtt{P} + \ominus\mathtt{B},\ \mathtt{One}\rangle\},$$
$$\{\langle 0 < \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle \oplus = \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle 0 \leqslant \oplus\mathtt{P},\ \mathtt{One}\rangle,$$
$$\langle 0 = \oplus\mathtt{P} + \ominus\mathtt{R} + \ominus\mathtt{B},\ \mathtt{One}\rangle\},$$
$$\{\langle 0 < \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle \oplus = \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle 0 \leqslant \oplus\mathtt{P},\ \mathtt{One}\rangle,$$
$$\langle 0 = \oplus\mathtt{P} + \ominus\mathtt{R} + \ominus\mathtt{B},\ \mathtt{One}\rangle,\ \langle 0 \leqslant \oplus\mathtt{R} + \oplus\mathtt{B},\ \mathtt{One}\rangle\},$$
$$\{\langle 0 < \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle \oplus = \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle 0 \leqslant \oplus\mathtt{P},\ \mathtt{One}\rangle,$$
$$\langle 0 = \oplus\mathtt{P} + \ominus\mathtt{R} + \ominus\mathtt{B},\ \mathtt{One}\rangle,\ \langle 0 \leqslant \oplus\mathtt{R} + \oplus\mathtt{B},\ \mathtt{One}\rangle, \langle 0 \leqslant \oplus\mathtt{R} + \oplus\mathtt{B},\ \mathtt{Any}\rangle\}\}.$$

As the fourth abstract store in the above multi-store subsumes the third store, we can simplify the output description of `mg` to

$$\{\{\langle 0 = \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle 0 = \oplus\mathtt{P} + \ominus\mathtt{B},\ \mathtt{One}\rangle\},$$
$$\{\langle 0 < \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle \oplus = \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle 0 \leqslant \oplus\mathtt{P},\ \mathtt{One}\rangle,$$
$$\langle 0 = \oplus\mathtt{P} + \ominus\mathtt{R} + \ominus\mathtt{B},\ \mathtt{One}\rangle\},$$
$$\{\langle 0 < \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle \oplus = \oplus\mathtt{T},\ \mathtt{One}\rangle,\ \langle 0 \leqslant \oplus\mathtt{P},\ \mathtt{One}\rangle,$$
$$\langle 0 = \oplus\mathtt{P} + \ominus\mathtt{R} + \ominus\mathtt{B},\ \mathtt{One}\rangle,\ \langle 0 \leqslant \oplus\mathtt{R} + \oplus\mathtt{B},\ \mathtt{One}\rangle,\ \langle 0 \leqslant \oplus\mathtt{R} + \oplus\mathtt{B},\ \mathtt{Any}\rangle\}\}.$$

Now, the reader may go back to the motivating discussion of Section 2, and check that the analysis is accurate enough to support every optimization step applied to the program of Example 2.1.

Finally, observe that a systematic normalization (removing redundancies through the ordering relation) may be applied at each step of the analysis to avoid the growth of abstract multi-stores.

4.5. Discussion

To conclude the section, it is instructive to point out a limitation of the domain `LSign`. On the one hand, consider the constraint store $\theta_1 = \{3 = x, 0 < x\}$ and its `LSign` abstraction $\beta_1 = \{\langle \oplus = \oplus x, \mathtt{One}\rangle, \langle 0 < \oplus x, \mathtt{One}\rangle\}$. It is easy to see that θ_1 is satisfiable (i.e. `Cis_sat`(θ_1) is true). Also we have that `Ais_sat`(β_1) is true, and so we can make the same conclusion from the abstract domain. On the other hand, consider the constraint store $\theta_2 = \{3 = x, 2 < x\}$ and its `LSign` abstraction $\beta_2 = \{\langle \oplus = \oplus x, \mathtt{One}\rangle, \langle \oplus < \oplus x, \mathtt{One}\rangle\}$. It is easy to see that `Cis_sat`(θ_2) is true, however `Ais_sat`(β_2) is false. While this does not violate the specification of `Ais_sat`, it means that the `LSign` domain is not able to approximate the store θ_2 sufficiently accurately for applications that need to reason about satisfiability in the abstract domain. Similar examples can be constructed to show loss of accuracy for conditional satisfiability. This suggests the need for a finer analysis than signs and the natural solution is to use intervals instead of signs to approximate numbers. This is explored further in the next section.

5. The abstract domain `LInt`

The abstract domain `LInt`, generalizes the domain `LSign` by using intervals instead of signs to abstract coefficients. Technically, the main difficulty arises because `LInt` is an infinite domain unlike `LSign`. This requires the definition of one more abstract operation, viz. the *widening* operation.

The section is organized as follows. Section 5.1 introduces the abstract objects of the domain `LInt`. Section 5.2 briefly presents the operations and applications of the

domain. The power domain and the widening are presented in Section 5.3. Section 5.4 concludes by discussing how `LInt` addresses the limitations of `LSign`.

5.1. Abstract objects and concretization

We consider the set of real numbers $\Re$ and its extension $\Re^\infty = \Re \cup \{-\infty, \infty\}$. The ordering on $\Re$ is extended to $\Re^\infty$, as usual. We also consider a finite subset $\mathscr{F}$ of $\Re$ containing 0 and the extension of $\mathscr{F}$ viz. $\mathscr{F}^\infty = \mathscr{F} \cup \{-\infty, \infty\}$. In practice, $\mathscr{F}$ is a set of floating point numbers or rational numbers used in the implementation.

The first key idea is the notion of an abstract constraint which abstracts a concrete constraint by replacing each coefficient by an interval over $\mathscr{F}^\infty$.

Definition 5.1 (*Intervals*). An *interval* is an element of

$$\texttt{Intv} = \begin{array}{l} \{[a_l, a_r] \mid a_l, a_r \in \mathscr{F} \ \wedge \ a_l \leqslant a_r\} \cup, \\ \{(a_l, a_r] \mid a_l \in \mathscr{F} \cup \{-\infty\} \ \wedge \ a_r \in \mathscr{F} \ \wedge \ a_l < a_r\} \cup, \\ \{[a_l, a_r) \mid a_l \in \mathscr{F} \ \wedge \ a_r \in \mathscr{F} \cup \{+\infty\} \wedge \ a_l < a_r\} \cup, \\ \{(a_l, a_r) \mid a_l \in \mathscr{F} \cup \{-\infty\} \ \wedge \ a_r \in \mathscr{F} \cup \{+\infty\} \ \wedge \ a_l < a_r\}. \end{array}$$

Intervals are denoted by the letter s, possible subscripted. The monotone concretization function $Cc : \texttt{Intv} \to 2^\Re$ is as expected. For instance, $Cc([a_l, a_r)) = \{c \mid c \in \Re \ \wedge \ a_l \leqslant c < a_r\}$.

We assume the existence of functions $\texttt{left} : \texttt{Intv} \to \mathscr{F}^\infty$ and $\texttt{right} : \texttt{Intv} \to \mathscr{F}^\infty$ which return respectively the left and right endpoint of an interval. We also assume the existence of Boolean functions `open_left` and `open_right` which indicate whether an interval is open to the left or to the right. In addition, it is convenient to define two relations $\texttt{increase} : \texttt{Intv} \times \texttt{Intv}$ and $\texttt{decrease} : \texttt{Intv} \times \texttt{Intv}$ as follows:

$$\begin{array}{l} \texttt{increase}(s_1, s_2) \Longleftrightarrow \exists c_1 \in Cc(s_1) \ \forall c_2 \in Cc(s_2) : c_1 > c_2, \\ \texttt{decrease}(s_1, s_2) \Longleftrightarrow \exists c_1 \in Cc(s_1) \ \forall c_2 \in Cc(s_2) : c_1 < c_2. \end{array}$$

The ordering on `Intv` is defined by $s_1 \sqsubseteq s_2 \Longleftrightarrow \neg\texttt{increase}(s_1, s_2) \wedge \neg\texttt{decrease}(s_1, s_2)$, and it satisfies the monotonicity criterion $s_1 \sqsubseteq s_2 \Rightarrow Cc(s_1) \subseteq Cc(s_2)$.

We also assume operations like $+, -, \times, \sqcup, \sqcap$ on intervals which are consistent approximations of the corresponding operations on $\Re^\infty$. For instance, $c_1 \in Cc(s_1) \wedge c_2 \in Cc(s_2) \Rightarrow c_1 + c_2 \in Cc(s_1 + s_2)$.

We say that an interval is *positive* (*negative*, resp.) if it contains only positive (negative, resp.) real numbers. Moreover, we say that an interval s is *zero* if $s = [0, 0]$. These properties are represented by the boolean functions `pos, neg, zer`. We also define the boolean function `contains_pos` (`contains_neg`, resp.) to indicate whether an interval contains at least one positive (negative resp.) number. Moreover, we define the boolean function `contains_zer` to indicate whether an interval contains the number zero. The definitions of operators, abstract constraints, multiplicities, abstract constraints with multiplicities, and abstract stores of the domain are completely parallel to those in the domain `LSign`. The only difference is that signs are replaced by intervals in the abstract constraints. We limit ourselves to some examples to explain these concepts in the domain `LInt`.

Example 5.1. The abstract constraint $(-\infty, +\infty) = [1,1]\mathtt{P} + [1,1]\mathtt{R}$ represents both the constraint $3 = \mathtt{P} + \mathtt{R}$ and $-3 = \mathtt{P} + \mathtt{R}$ but not the constraint $3 = 2\mathtt{P} + 3\mathtt{R}$. The abstract constraint with multiplicity $\langle (-\infty, +\infty) = [1,1]\mathtt{P} + [1,1]\mathtt{R},\ \mathtt{One}\rangle$ represents only multisets of size 1, e.g., $\{3 = \mathtt{P} + \mathtt{R}\}$. $\langle 0 \leqslant [1.01, +\infty)\mathtt{P} + (-\infty, -1]\mathtt{R},\ \mathtt{Any}\rangle$ represents multisets of any size, e.g., $\emptyset$, $\{0 \leqslant 3\mathtt{P} - \mathtt{R}\}$ and $\{0 \leqslant 3\mathtt{P} - \mathtt{R}, 0 \leqslant 2\mathtt{P} - 3\mathtt{R}\}$. The abstract store $\beta = \{\langle (-\infty, +\infty) = [1,1]\mathtt{P} + [1,1]\mathtt{R},\ \mathtt{One}\rangle\ ,\ \langle 0 \leqslant [1.01, +\infty)\mathtt{P} + (-\infty, -1]\mathtt{R},\ \mathtt{Any}\rangle\}$ represents constraint stores with at least one constraint, and their equivalence classes. For example $\{3 = \mathtt{P} + \mathtt{R}\} \in Cc_i(\beta)$ and $\{3 = \mathtt{P} + \mathtt{R}\ , 0 \leqslant 2\mathtt{P} - 3\mathtt{R}\} \in Cc_i(\beta)$. Further, $\{3 = \mathtt{P} + \mathtt{R},\ 9 \leqslant 5\mathtt{P}\} \in Cc(\beta)$ because $\{3 = \mathtt{P} + \mathtt{R},\ 9 \leqslant 5\mathtt{P}\} \leftrightarrow \{3 = \mathtt{P} + \mathtt{R}, 0 \leqslant 2\mathtt{P} - 3\mathtt{R}\}$.

5.2. Operations and applications

The algorithms for various operations (ordering, addition of a constraint, upper bound and projection) as well as the applications (satisfiability and conditional satisfiability) of `LInt` are for the most part identical to the corresponding algorithms in `LSign`. The only difference is that the various operations on signs are replaced by the corresponding operations on intervals. For example, a test $\sigma[v] = \oplus$ would be replaced by the test $\mathtt{pos}(\sigma[v])$, while an assignment $\sigma[v] := 0$ would be replaced by the assignment $\sigma[v] := [0,0]$. The only algorithm that undergoes a non-trivial change is the algorithm for operation `Asplit_top`. It can be more precise due to the more precise information available about the coefficient of the variable being eliminated. The algorithm for `Asplit_top` in `LInt` is given in Fig. 6.

```
Asplit_top(β, v) {
if β = ∅ return ∅;
else let   β = {γ} ∪ β' ∧ γ = ⟨σ, μ⟩ ∉ β'
    γ⁰ = ⟨σ⁰, μ ⊔ ZeroOrOne⟩
    γ⁺ = ⟨σ⁺, μ ⊔ ZeroOrOne⟩
    γ⁻ = ⟨σ⁻, μ ⊔ ZeroOrOne⟩
    σ⁰ = σ except that σ⁰[v] = [0,0]
    σ⁺ = σ except that σ⁺[v] = σ[v] ⊓ (0, +∞)
    σ⁻ = σ except that σ⁻[v] = σ[v] ⊓ (−∞, 0) in
    case not (pos(σ[v]) ∨ neg(σ[v]) ∨ zer(σ[v])):
        β'' := ∅
        if contains_zer(σ[v])
            β'' := β'' ⊎ γ⁰;
        if contains_pos(σ[v])
            β'' := β'' ⊎ γ⁺;
        if contains_neg(σ[v])
            β'' := β'' ⊎ γ⁻;
        return Asplit_top(β',v) ⊎ β'';
    otherwise:
        return Asplit_top(β',v) ⊎ γ;
}
```

Fig. 6. Modified `Asplit_top` algorithm for `LInt`.

5.3. The power domain $2^{\texttt{LInt}}$ and widening

Just like LSign, the upper bound operation in LInt may not be sufficiently accurate to perform a practical analysis of CLP programs. It may become necessary to move to the power domain $2^{\texttt{LInt}}$ in order to get the required accuracy. The definition of the various concepts in the domain $2^{\texttt{LInt}}$ is completely parallel the corresponding definitions in the domain $2^{\texttt{LSign}}$. However, as $2^{\texttt{LInt}}$ is an infinite domain, it becomes necessary to introduce a *widening* operator.[8] The use of widening operators was proposed in Ref. [6], further discussed in Ref. [7], and has been used in domains such as type graphs for Prolog [40].

Naive widenings for $2^{\texttt{LInt}}$ induce a substantial loss of precision, even on small examples. The main contribution of this section is to show how LSign can be used to guide the widening of LInt. The basic intuition behind our widening is to try to guess where the constraint stores are growing. A fundamental observation here is the fact that, in general, the growth preserves the shape of the LInt constraint store when it is viewed as a LSign constraint.

The definition of the widening operator proceeds systematically at each level of abstract objects. For each abstract object, it is convenient to define the *shape* of that object, which is obtained by replacing intervals in that object by the corresponding signs.

Definition 5.2 (*Shape and widening of intervals*). The shape of an interval s is defined as

$$\texttt{shape}(s) = \begin{cases} \oplus & \text{if } \texttt{pos}(s), \\ \ominus & \text{if } \texttt{neg}(s), \\ 0 & \text{if } \texttt{zer}(s), \\ \top & \text{otherwise.} \end{cases}$$

Let s_{old} and s_{new} be intervals s.t. $\texttt{shape}(s_{new}) = \texttt{shape}(s_{old})$. Then

$$s_{new} \nabla s_{old} = s' \text{ such that,}$$

$$\texttt{left}(s') = \begin{cases} 0 & \text{if } \texttt{decrease}(s_{new}, s_{old}) \wedge \texttt{pos}(s_{old}), \\ -\infty & \text{if } \texttt{decrease}(s_{new}, s_{old}) \wedge \neg\texttt{pos}(s_{old}), \\ \texttt{left}(s_{old}) & \text{otherwise} \end{cases}$$

$$\texttt{open\_left}(s') = \texttt{decrease}(s_{new}, s_{old}) \vee \texttt{open\_left}(s_{old}),$$

$$\texttt{right}(s') = \begin{cases} 0 & \text{if } \texttt{increase}(s_{new}, s_{old}) \wedge \texttt{neg}(s_{old}), \\ \infty & \text{if } \texttt{increase}(s_{new}, s_{old}) \wedge \neg\texttt{neg}(s_{old}), \\ \texttt{right}(s_{old}) & \text{otherwise} \end{cases}$$

$$\texttt{open\_right}(s') = \texttt{increase}(s_{new}, s_{old}) \vee \texttt{open\_right}(s_{old})$$

The widening is defined only for intervals that have the same shape, an can be seen as an extension of the widening on interval domains as defined in Ref. [7]. We discuss

[8] In fact, it is necessary to define a widening for the LInt domain as well, but we shall focus on the $2^{\texttt{LInt}}$ domain, as it is used in our compiler.

how the left endpoint of the intervals is widened. The right endpoint is similar. If the new interval s_{new} is growing at the left endpoint relative to the old interval s_{old}, the widened left endpoint is set to the minimum possible value that does not alter the shape of the interval. This means that if a positive interval is growing at the left endpoint, its widened left endpoint is set to 0 and made open. If a non-positive interval is growing at the left endpoint, its widened left endpoint is set to $-\infty$. Otherwise the left endpoint is not changed. The reason for distinguishing between positive and non-positive intervals is to make sure that the widened interval has the same shape as the original intervals. Also the intervals are not made smaller by the widening and so the following lemma applies.

Lemma 5.1. *Let s_{old} and s_{new} be intervals s.t.* $\mathtt{shape}(s_{new}) = \mathtt{shape}(s_{old})$. *Then*
(i) $\mathtt{shape}(s_{old}) = \mathtt{shape}(s_{new} \nabla s_{old})$.
(ii) $c \in Cc(s_{old}) \vee c \in Cc(s_{new}) \Rightarrow c \in Cc(s_{new} \nabla s_{old})$.

The notion of shape and widening can be easily lifted to abstract constraint with multiplicities, abstract stores, and abstract multistores (see Ref. [34] for complete details). For each such abstract object, normalization operations are introduced that avoid redundancies (with respect to the shape), leading to the following definitions:

Definition 5.3 (*Normalized abstract multistore*). An abstract multistore α is said to be normalized if
- $\forall \beta \in \alpha : \forall \gamma_1, \gamma_2 \in \beta : \mathtt{shape}(\gamma_1) \neq \mathtt{shape}(\gamma_2)$;
- $\forall \beta_1, \beta_2 \in \alpha : \mathtt{shape}(\beta_1) \neq \mathtt{shape}(\beta_2)$.

Given an abstract multistore α, it is possible to transform it into a corresponding normalized multistore $\mathtt{normal}(\alpha)$ such that $\theta \in Cc(\alpha) \Rightarrow \theta \in Cc(\mathtt{normal}(\alpha))$.

Definition 5.4 (*Shape and widening of abstract multistores*). The shape of an normalized abstract multistore α is defined as $\mathtt{shape}(\alpha) = \{\mathtt{shape}(\beta) \mid \beta \in \alpha\}$.

Let α_{old} and α_{new} be normalized abstract multistores. Then

$$\alpha_{new} \nabla \alpha_{old} = \begin{cases} \alpha_{old}, & \text{if } \alpha_{new} \sqsubseteq \alpha_{old}, \\ \{\beta_{old} \mid \beta_{old} \in \alpha_{old},\ \mathtt{shape}(\beta_{old}) \notin \mathtt{shape}(\alpha_{new})\} \cup & \text{otherwise,} \\ \{\beta_{new} \mid \beta_{new} \in \alpha_{new},\ \mathtt{shape}(\beta_{new}) \notin \mathtt{shape}(\alpha_{old}\} \cup & \\ \{\beta_{new} \nabla \beta_{old} \mid \beta_{new} \in \alpha_{new},\ \beta_{old} \in \alpha_{old},\ \mathtt{shape}(\beta_{new}) = \mathtt{shape}(\beta_{old})\}. & \end{cases}$$

Intuitively, the widening for abstract multistores is a generalization of the upper bound operation. The abstract stores belonging to α_{old} and α_{new} need to be added to $\alpha_{new} \nabla \alpha_{old}$, however if there are two abstract stores with the same shape, their widening needs to be computed first. The following lemma states that the widening for abstract multistores preserves the normalized form and that the widened multistore's concretization includes the concretizations of α_{old} and α_{new}.

Lemma 5.2. *Let α_{old} and α_{new} be normalized abstract multistores. Then*
(i) *$\alpha_n \nabla \alpha_{old}$ is normalized.*
(ii) $\theta \in Cc(\alpha_{old}) \vee \theta \in Cc(\alpha_{new}) \Rightarrow \theta \in Cc(\alpha_{new} \nabla \alpha_{old})$. The following theorem states the correctness of the operator ∇.

Theorem 5.1 (Widening). *Operation* ∇ *is a widening operator.*

To conclude the section, we show the resulting output description for the mortgage program `mg/4` of Example 2.1 on this domain.

Example 5.2 (*Computation of* $2^{\mathtt{LInt}}$ *Output Description for* `mg/4`). The abstract substitution describing the output of the first clause is

$$\{\{\langle [0,0] = [1,1]\mathtt{T}, \mathtt{One}\rangle, \langle [0,0] = [1,1]\mathtt{P} + [-1,-1]\mathtt{B}, \mathtt{One}\rangle\}\}.$$

At the end of the analysis of both clauses, requiring the application of the widening operation, the computation leads to the following multistore, which is the fixpoint of the computation and represents the output of the predicate `mg`:

$$\begin{array}{l}
\{\{\langle [0,0] = [1,1]\mathtt{T}, \mathtt{One}\rangle, \langle [0,0] = [1,1]\mathtt{P} + [-1,-1]\mathtt{B}, \mathtt{One}\rangle\},\\
\{\langle [0,0] < [1,1]\mathtt{T}, \mathtt{One}\rangle, \langle [1,1] = [1,1]\mathtt{T}, \mathtt{One}\rangle,\\
\quad \langle [0,0] \leqslant [1,1]\mathtt{P}, \mathtt{One}\rangle, \langle [0,0] = [1.01,1.01]\mathtt{P} + [-1,-1]\mathtt{R} + [-1,-1]\mathtt{B}, \mathtt{One}\rangle\},\\
\{\langle [0,0] < [1,1]\mathtt{T}, \mathtt{One}\rangle, \langle [0,0] \leqslant [1,1]\mathtt{P}, \mathtt{One}\rangle, \langle [2,3] = [1,1]\mathtt{T}, \mathtt{One}\rangle,\\
\quad \langle [0,0] = [1.0201,103.0301]\mathtt{P} + [-303.01,-2.01]\mathtt{R} + [-100,-1]\mathtt{B}, \mathtt{One}\rangle,\\
\quad \langle [0,0] \leqslant [1,201]\mathtt{R} + [1,100]\mathtt{B}, \mathtt{One}\rangle, \langle [0,0] \leqslant [1,201]\mathtt{R} + [1,100]\mathtt{B}, \mathtt{Any}\rangle\},\\
\{\langle [0,0] < [1,1]\mathtt{T}, \mathtt{One}\rangle, \langle [0,0] \leqslant [1,1]\mathtt{P}, \mathtt{One}\rangle, \langle [3,+\infty) = [1,1]\mathtt{T}, \mathtt{One}\rangle,\\
\quad \langle [0,0] = [1.030301,+\infty)\mathtt{P} + (-\infty,-3.0301]\mathtt{R} + (-\infty,-1]\mathtt{B}, \mathtt{One}\rangle,\\
\quad \langle [0,0] \leqslant [1,201]\mathtt{R} + [1,100]\mathtt{B}, \mathtt{One}\rangle, \langle [0,0] \leqslant [1,201]\mathtt{R} + [1,100]\mathtt{B}, \mathtt{Any}\rangle,\\
\quad \langle [0,0] \leqslant [1.01,+\infty)\mathtt{P} + (-\infty,-1]\mathtt{R}, \mathtt{One}\rangle,\\
\quad \langle [0,0] \leqslant [1.01,+\infty)\mathtt{P} + (-\infty,-1]\mathtt{R}, \mathtt{Any}\rangle\}\}
\end{array}$$

Comparing this multistore with the one shown in Example 4.17, we may observe how more accurate the analysis using $2^{\mathtt{LInt}}$ is with respect to the analysis on $2^{\mathtt{LSign}}$. For instance, in the first two stores (that correspond strictly, in the two examples), there is no loss of information when using $2^{\mathtt{LInt}}$ with respect to the concrete computation, whereas $2^{\mathtt{LSign}}$ analysis immediately looses track of any numeric value.

5.4. Discussion

The domain `LInt` enables us to overcome the limitation of the domain `LSign` that was pointed out in the previous section. Consider the constraint store $\theta = \{3 = x, 2 < x\}$. Its `LSign` abstraction is $\beta = \{\langle \oplus = \oplus x, \mathtt{One}\rangle, \langle \oplus < \oplus x, \mathtt{One}\rangle\}$. While θ is satisfiable, `Ais_sat`(β) is false because the abstract store obtained by projecting all the variables is $\{\langle \top < 0, \mathtt{One}\rangle\}$. Moving to the domain `LInt`, the abstraction of θ is $\beta' = \{\langle [3,3] = [1,1]x, \mathtt{One}\rangle, \langle [2,2] < [1,1]x, \mathtt{One}\rangle\}$. Projecting all the variables gives the abstract store $\{\langle [-1,-1] < 0, \mathtt{One}\rangle\}$ and so `Ais_sat`(β') is true, which represents the concrete operation more accurately. Similar examples can be constructed for the other abstract applications such as conditional satisfiability.

6. Preliminary experimental results

The purpose of this section is to give very preliminary evidence that the domain $2^{\mathtt{LSign}}$ is sufficiently precise to perform the intended optimizations. It shows that an optimizing compiler can indeed use the domain and perform the intended optimizations on small programs and it gives the magnitude of the speed-ups. The section

also gives some preliminary information on the price to pay when using $2^{\texttt{LInt}}$ instead of $2^{\texttt{LSign}}$. The compilation times given in this section should be interpreted with care. The compiler is not incremental and restarts the analysis as soon as a reordering takes place. Obviously, a practical compiler should be incremental and the techniques presented in Ref. [17] should be helpful here to obtain a fast implementation. Our benchmarks are relatively small, since most large CLP($\Re_{Lin}$) programs use first-order terms in addition to linear constraints and our analyzer is not able to handle them at this stage. Most of the programs are also multi-directional and they are run with various modes: u stands for an unconstrained variable while f stands for a fixed variable. Program Integer(N) is used to verify if 25 000 is an integer and to generate the first 250 integers. The next three programs, Exp(N,E), Sum(N,S) and Fibonacci(N,F) are programs that compute $2^{\texttt{N}}$, the sum of the first N integers, and the $\texttt{N}^{th}$ Fibonacci number, respectively. Mortgage relates the various parameters of a mortgage computation, and we have two versions of it. The first is the running example used in the paper. The second is a syntactically nonlinear version which has the interest rate as an argument. We have used an interest rate of 1% per month and a monthly repayment of 2 units; the final balance is unconstrained. The value of the principal and time period vary to illustrate various tradeoffs in the optimizations. Ode-Euler [29] is a program solving the ordinary differential equation $y' = t$. Triangular is a benchmark that involves simultaneously solving a sparse system of N equations, subsystems of which are in upper triangular form. Table 1 summarizes the usage modes of the various test programs.

Table 1
Test programs: description of usage in various modes

Program	Mode	Description
Integer	f	Is 25000 an integer?
	u	Generate $0 \ldots 250$
Exp	fu	Compute 2^{25}
	uf	Compute lg 2^{25}
	uu	Generate $(0,1) \ldots (25, 2^{25})$
Sum	fu	Compute $0 + 1 + \cdots + 500$
	uf	Find N s.t. $0 + 1 + \cdots + N = 125250$
	uu	Generate $(0,0) \ldots (500, 125250)$
Fibonacci	fu	Compute 15th Fibonacci number
	uf	Find N s.t. 987 is Nth Fibonacci number
	uu	Generate $(0,1) \ldots (15, 987)$
Mortgage (Linear)	fffu (1)	Principal = 100, Time = 50; find Balance
	fffu (2)	Principal = 200, Time = 100; find Balance
	fufu (1)	Principal = 100, Time = 0 ... 50; find Balance
	fufu (2)	Principal = 200, Time = 0 ... 100; find Balance

	ffffu (2)	Principal = 200, Time = 100; find Balance
	fuffu (1)	Principal = 100, Time = 0 ... 50; find Balance
	fuffu (2)	Principal = 200, Time = 0 ... 100; find Balance
Ode-Euler	ffffu	Compute final y value
	fufff	Compute initial y value
	fuffu	Relate initial and final y values
Triangular, 2000		Solve N equations, N = 2000
4000		Solve N equations, N = 4000
8000		Solve N equations, N = 8000

The benchmarks are used to compare the optimizing compiler (Opt.) with the standard compiler (Unopt.). Both compilers generate code for the same runtime system which is a WAM-based system with special instructions for tests and assignments. The architecture of the system was described in Ref. [39]. The runtime system uses infinite precision integers to guarantee numerical stability. Table 2 reports the computation times (in milliseconds on a SUN-SPARC-10) for the optimized and unoptimized versions of the benchmarks for various modes on $2^{\mathtt{LSign}}$. It also gives the ratio of the unoptimized execution time to the optimized execution time (*speedup*). The table also specifies which optimizations have been performed. `REO` indicates that constraints were reordered, `REF` indicates that constraints were refined to tests or assignments and `REM` indicates that (redundant) constraints were removed from the program. The final column in the table indicates whether the optimizations enabled the execution to bypass the constraint solver entirely (i.e perform only tests and assignments in the engine and interface). A $\surd$ indicates that the unoptimized program utilized the constraint solver to perform constraint solving, while the optimized program bypassed the constraint solver entirely. For all these programs, $2^{\mathtt{LSign}}$-analysis is sufficient to get maximal precision for reordering, and passing to $2^{\mathtt{LInt}}$ does not bring any improvement with that respect. However, it is sufficient to slightly modify their code (e.g. moving the basic case

Table 2
Comparison of running times in ms.: optimized vs unoptimized using $2^{\mathtt{LSign}}$-analysis

from 0 to 1) to see that $2^{\texttt{LInt}}$ still supports the optimization while LSign looses most of its accuracy.

The speedups vary from 1.00 on one of the Exp queries to 15.48 on the Triangular program, when 8000 equations are solved. Seven programs exhibit speedups of at least 10, while eleven programs exhibit speedups lower than two. The average speedup observed was 5.68.

Finally, we investigated the price the pay to move from $2^{\texttt{LSign}}$ to $2^{\texttt{LInt}}$. Table 3 gives the optimization time (in milliseconds) for $2^{\texttt{LSign}}$, separately for each of the three phases, as well as for the total of the three phases; then, it compares the optimization times for the benchmarks when $2^{\texttt{LInt}}$ is used in the analyzer instead of $2^{\texttt{LSign}}$. For our benchmarks, the average penalty paid by the $2^{\texttt{LInt}}$ analysis over the $2^{\texttt{LSign}}$ analysis is a factor of 7.39.

7. Conclusions

This paper has studied two abstract domains, LSign and LInt, which can be used at compile time to determine when it is safe to reorder CLP programs. As far as LSign is concerned, the paper redefined the domain of [28] to simplify the correctness proofs. It proposed a new ordering capturing the intended meaning of [28] computable in polynomial time. It proposed a more precise algorithm for projection. Finally, it discussed how LSign can be used to detect the conditional satisfiability of constraint stores, an operation which is fundamental to reorder CLP($\Re_{Lin}$) programs.

This operation, which was never discussed previously, was shown to raise some subtle practical issues which are studied at length. As far as the new domain `LInt` is concerned, the paper proposed in particular a precise widening operator. The paper also described some very preliminary evidence showing that the domains are precise enough to perform the intended optimizations on small programs.

There are of course many avenues for future research. Of immediate concern is the development of a fast and incremental optimizing compiler using the technology described in Ref. [17]. Equally important are the enhancement of the domains to support first-order terms, and their integration in the generic `Pattern` domain [5] to optimize the interaction with unification constraints. These developments will make it possible to apply the domains on large programs and to give a definitive assessment on their practical value.

Acknowledgements

We are grateful to the anonymous referees for insightful suggestions. Agostino Cortesi is partially supported by the Italian MURST project N. 9701248444-044.
