Artificial Intelligence

University of Venice, Italy

a.a. 2013/14

Prof. Marcello Pelillo
What is Artificial Intelligence (AI)?

There is no universally accepted definition of Artificial Intelligence. A tentative one is the following:

**AI is the endeavor of building an intelligent artifact**

But... what is “intelligence”?

Some definitions:

- It is the ability to learn (Buckingam, 1921)
- This faculty is judgment, otherwise called good sense, practical sense, initiative, the faculty of adapting one's self to circumstances (Binet and Simon, 1961)
- It is the ability to perform well in an intelligence test (Boring, 1961)
Nel 1950, Alan M. Turing proposed an operational definition of intelligence (the “Turing test”).
Can Machines Think? The Turing Test
(From, A. M. Turing, Computer Machinery and Intelligence, 1950)

« I propose to consider the question, "Can machines think?" This should begin with definitions of the meaning of the terms "machine" and "think." The definitions might be framed so as to reflect so far as possible the normal use of the words, but this attitude is dangerous. If the meaning of the words "machine" and "think" are to be found by examining how they are commonly used it is difficult to escape the conclusion that the meaning and the answer to the question, "Can machines think?" is to be sought in a statistical survey such as a Gallup poll. But this is absurd.

Instead of attempting such a definition I shall replace the question by another, which is closely related to it and is expressed in relatively unambiguous words. »
The Imitation Game

« The new form of the problem can be described in terms of a game which we call the 'imitation game.' It is played with three people, a man (A), a woman (B), and an interrogator (C) who may be of either sex. The interrogator stays in a room apart from the other two. The object of the game for the interrogator is to determine which of the other two is the man and which is the woman. He knows them by labels X and Y, and at the end of the game he says either "X is A and Y is B" or "X is B and Y is A." The interrogator is allowed to put questions to A and B thus:

C: Will X please tell me the length of his or her hair?

Now suppose X is actually A, then A must answer. It is A's object in the game to try and cause C to make the wrong identification. His answer might therefore be:

"My hair is shingled, and the longest strands are about nine inches long." »
« In order that tones of voice may not help the interrogator the answers should be written, or better still, typewritten. The ideal arrangement is to have a teleprinter communicating between the two rooms. Alternatively the question and answers can be repeated by an intermediary. **The object of the game for the third player (B) is to help the interrogator.** The best strategy for her is probably to give truthful answers. She can add such things as "I am the woman, don't listen to him!" to her answers, but it will avail nothing as the man can make similar remarks.

**We now ask the question, "What will happen when a machine takes the part of A in this game?"** Will the interrogator decide wrongly as often when the game is played like this as he does when the game is played between a man and a woman?

**These questions replace our original, "Can machines think?" »**
An Imaginary Dialogue

Q: Please write me a sonnet on the subject of the Forth Bridge.

A: Count me out on this one. I never could write poetry.

Q: Add 34957 to 70764.

A: (Pause about 30 seconds and then give as answer) 105621.

Q: Do you play chess?

A: Yes.

Q: I have K at my K1, and no other pieces. You have only K at K6 and R at R1. It is your move. What do you play?

A: (After a pause of 15 seconds) R-R8 mate.
Passing the Turing Test

To pass the test a machine must possess the following skills:

**Natural language processing**
- to interact with the interrogator

**Knowledge representation**
- to memorize information before and during the dialogue

**Automatic reasoning**
- to use the acquired knowledge to answer the question and draw conclusions

**Learning**
- to adapt to new situations
The “Total” Turing Test

The machine can access an audio/video feed so that the interrogator can test its perception skills; further, the interrogator can pass objects to be manipulated.

This requires:

**Perception**
- to analyze and comprehend images and sounds

**Robotics**
- to manipulate objects and navigate
Our most detailed information of Babbage's Analytical Engine comes from a memoir by Lady Lovelace (1842). In it she states,

“The Analytical Engine has no pretensions to originate anything. It can do whatever we know how to order it to perform”

But, machines can learn.

Arthur Samuel (1901-1990) wrote a checkers-playing program for the IBM 701 in 1952. His first learning program was completed in 1955 and demonstrated on television in 1956.

Very soon the program systematically start to beat its inventor…
There are a number of results of mathematical logic which can be used to show that there are limitations to the powers of discrete-state machines.

The best known of these results is known as Godel's theorem (1931) and shows that in any sufficiently powerful logical system statements can be formulated which can neither be proved nor disproved within the system, unless possibly the system itself is inconsistent.
The Argument from Consciousness

This argument is very, well expressed in Professor Jefferson's Lister Oration for 1949, from which I quote:

« Not until a machine can write a sonnet or compose a concerto because of thoughts and emotions felt, and not by the chance fall of symbols, could we agree that machine equals brain—that is, not only write it but know that it had written it. »
Searle’s Chinese Room
Strong and Weak AI

Weak AI:
Can a machine exhibit intelligent behavior?

Strong AI:
Can a machine have self awareness?

Engineering vs Scientific attitudes towards AI.

Two Approaches to AI

Symbolic (declarativism)  Sub-symbolic (non-declarativism)

Deals with:
Theorem proving,
problem solving,
games, reasoning, etc.

Deals with:
Pattern recognition,
perception, learning,

Psychology  Neurobiology

Serial systems  Parallel systems
Some History
Early Attempts (1943-1956)

1943: McCulloch and Pitts propose a model for an artificial neuron and analyze its properties.

1949: Donald Hebb proposes a learning mechanism in the brain, still of great interest.

1950-53: Shannon and Turing work (independently) on chess-playing programs.

1951: Minsky and Edmonds develop the first “neural” computer.

1956: Newell e Simon develop the “Logic Theorist”
A PROPOSAL FOR THE DARTMOUTH SUMMER RESEARCH PROJECT ON ARTIFICIAL INTELLIGENCE

J. McCarthy, Dartmouth College
M. L. Minsky, Harvard University
N. Rochester, I.B.M. Corporation
C. E. Shannon, Bell Telephone Laboratories

August 31, 1955

We propose that a 2 month, 10 man study of artificial intelligence be carried out during the summer of 1956 at Dartmouth College in Hanover, New Hampshire. The study is to proceed on the basis of the conjecture that every aspect of learning or any other feature of intelligence can in principle be so precisely described that a machine can be made to simulate it. An attempt will be made to find how to make machines use language, form abstractions and concepts, solve kinds of problems now reserved for humans, and improve themselves. We think that a significant advance can be made in one or more of these problems if a carefully selected group of scientists work on it together for a summer. […]
1961: Newell and Simon develop General Problem Solver (GPS)

1952-: Samuel develops a checker playing game

1957: First attempts at automatic translation

1958: McCarthy invents LISP

1963 - : Minsky and students study problems on micro-worlds (es., ANALOGY, SHRDLU)

1962: Rosenblatt develops the Perceptron, a neural net that learns from examples
1966: Financing to “automatic translation” projects in the USA is canceled

1969: Minsky and Papert publish Perceptrons, where they show that the Rosenblatt model cannot solve some very simple problems

1971-72: Cook and Karp develop the computational complexity theory, showing that a lot of problems are “intractable” (NP-complete).
1969: Feigenbaum et al. (Stanford) develop DENDRAL, an ES for making predictions on molecular structures

1976: MYCIN, an ES with some 450 rules for the diagnosis of infectious diseases

1979: PROSPECTOR, an ES for mineral explorations

1982: R1, a commercial ES for configuring DEC VAX systems
1982: Hopfield (Caltech) develops a neural model based on the analogy with physical (ferromagnetic) systems.

1985: Hopfield and Tank applied their model to “solve” intractable (NP-complete) problems.

1986: The PDP group (re)introduces back-propagation, a learning algorithm for layered (feed-forward) neural networks, thereby overcoming the limitation of Perceptrons.

1987: Sejnowski and Rosenberg develop NETtalk, a neural network that “learns” to talk.
NETtalk: A Neural Net that Learns to Talk

Biometry

Biometry develops techniques for the automatic reocognition of a person’s identity.

**Typical biometric information**

**Physiological:**
- Face
- Fingerprints
- Voice
- Retina
- Iris
- Hands
- DNA
- ...

**Behavioral:**
- Signature
- Keystroke
- Gait
- ...
- ...
« A comprehensive immigration reform must include a better system for verifying documents and work eligibility. A key part of that system should be a new identification card for every legal foreign worker. This card should use biometric technology. »

George W. Bush
